**077200 CONSTRUCTION SITE WORKERS HELMETS.** Instrumented impact tests were carried out on various types of industrial safety helmets manufactured to BS5240, and force versus deflection graphs produced. A simple mathematical model was used to explain the results obtained when helmets are hit on the top. The model can then be used to protect the effect of modifying the shell stiffness or suspension stiffness. It also predicts the large force oscillations at 300 Hz caused by the striker exciting the resonant frequency of the shell mass/suspension spring system. It was concluded that while the helmets perform adequately during top impacts, the protection given at the sides, front and back of the helmet is so poor that a redesign is necessary. (Author abstract) 8 refs.

**077201 DURABILITY OF FIREFIGHTER'S PROTECTIVE CLOTHING TO HEAT AND LIGHT.** Fabrics used in firefighter's protective clothing were exposed to simulated sunlight from a xenon arc Weather-Ometer and heat in a forced air circulating oven, and the resulting changes in properties were measured. Outer shell fabrics Of Nomex III, Zirpro flame resistant wool and PBI/Kevlar were all susceptible to light and underwent marked reductions in tensile tearing strength. Heat exposure resulted in a significant reduction in the tearing strength of all outer shell fabrics while increasing the tearing strength of moisture barrier fabrics. A polyamid/flame resistant viscose blend was extremely sensitive to heat exposure, undergoing a substantial loss in tearing strength and appreciable thermal shrinkage. Zirpro flame resistant wool was particularly sensitive to temperatures greater than 230°C. Although both light and heat caused losses in physical strength, there was no noticeable reduction in the flame resistance or thermal protective performance of the individual fabrics and garment assemblies studied. (Edited author abstract) 12 refs.

**077202 PROTECTION WITH SUITS AND BREATHING APPARATUS.** This article discusses the problems associated with the combined use of breathing apparatus sets and chemical protection clothing, and means of reducing stress in fire-fighting underground. The user requirements correspond to the well-known principles for chemical protection suits. One currently available fabric combination, which was developed for firemen on the basis of these principles, consists of a chemical protection suit having an outer coat of fluorocarbon elastomer (Viton) and an inner coat consisting of chloroprene rubber. This suit represents the technically feasible compromise for a wide range of many different application criteria.

## Radiation Effects

**077204 BIOLOGISCHE WIRKUNG ELEKTROMAGNETISCHER 50-HZ-FELDER AUF DEN MENSCHEN.** [Biological Effects of Electromagnetic 50 Hz Fields on Humans]. For several years apprehensions have been voiced on the health dangers from the electrical and magnetic fields of plants of electricity utilities. Thermic effects, such as those from the expressly restricted high frequency fields of communications technology, are excluded from the low frequency 50 Hz fields. Dangerous irritant effects from induced body currents could not be established, despite worldwide research. Consequently, reliable evidence on the harmless limits of directly effective 50 Hz fields is today available. (Author abstract) In German. 41 refs.

**077205 CONTROLLING OCCUPATIONAL EXPOSURE AT FINLAND'S LOVIISA PWRS.** The two VVER-440 PWRS at Loviisa, in commercial operation since 1977 and 1980 respectively, have distinguished themselves by recording annual collective doses, including both plant staff and outside contractors, of less than 0.9man-Sv per unit. Reasons for this low exposure include plant design features, waste handling arrangements, administrative procedures, and, perhaps most important, short annual outages. (Author abstract). 5 Refs.

Wahlstrom, Bjorn (Imatran Voima Oy, Loviisa, Finl). *Nucl Eng Int* v 33 n 409 Aug 1988 4p.

**077206 BETTER MONITORING OF PERSONNEL FOR SURFACE CONTAMINATION.** In recent years there has been a marked increase in the use of high performance installed personnel monitors employing large arrays of detectors to examine people for surface contamination automatically and rapidly. The IPM 8 from NE Technology promises improved quality of monitoring in radiation controlled zones, in temporary work areas and older buildings, as well as at main exits. (Edited author abstract).

## Rating

**077207 ENGINEERING AN APPROACH TO PERFORMANCE EVALUATIONS.** Based on performance management in engineering, it is possible to extract a new definition of performance management, which includes a pre-determined definition of performance standards, pre-defined performance levels, performance evaluated by the pre-defined standards, planning and reworking the system based upon the evaluation results. Together, these steps form this definition: performance management is the process of planning for the future, not criticizing the past. The article discusses each of these points, along with

conducting an evaluation, performance monitoring, and other aspects of the subject.

**Scheduling** See Also MOTOR BUS TRANSPORTATION—Personnel.

**077208 COST OF CONSECUTIVITY IN THE (5, 7) CYCLIC STAFFING PROBLEM.** The (5, 7) cyclic staffing problem is the problem of finding the least number of workers assigned to a 7 day cyclic schedule, so that sufficient workers are present during day *i* to meet requirement *b<sub>i</sub>*, and each person works a shift of 5 consecutive days and is idle for the other 2. We derive an expression for the minimal workforce size in the problem in terms of the *b<sub>i</sub>*'s. This result is interesting because it shows the extra number of workers needed by insisting that each person's idle days are consecutive. (Author abstract) 8 refs.

**077209 DYNAMIC JOB-ASSIGNMENT POLICY.** This report considers a dynamic job-assignment policy making use of online information for assignment. This policy attempts to achieve a good skill match between jobs and operators, and to eliminate unnecessary assignments. To fulfill this policy, a two-part assignment program is proposed: an algorithm for job matching and a set of ad hoc rules. The matching algorithm is well established in literature, but the ad hoc rules are application-dependent. Discussion here concentrates on the ad hoc rules and online data collection. **077210 GENERATING ACCEPTABLE SHIFT-WORKING SCHEDULES.** When a factory operates a shift system of working, the work patterns are usually laid down at the start and adhered to for long periods. In this case study, small out-stations with frequent changes in manning require the frequent generation of new schedules. Producing and co-ordinating such schedules with the workforce can be a time-consuming task. Hence a computer routine was devised which takes over the generation. An interesting feature is that several feasible routines are generated, allowing the final decision to be taken by the workforce itself. (Author abstract). 5 Refs.

**Security Systems**

**077211 PERFORMANCE EVALUATION OF PERSONNEL IDENTITY VERIFIERS.** Personnel identity verification devices, which are based on the examination and assessment of a body feature or a unique repeatable personal action, are steadily improving. These biometric devices are becoming more practical with respect to accuracy, speed, user compatibility, reliability and cost, but more development is necessary to satisfy the varied and sometimes ill-defined future requirements of the security industry. In an attempt to maintain an awareness of the availability and the capabilities of identity verifiers for the DOE security community, Sandia Laboratories continues to comparatively evaluate the capabilities and improvements of developing devices. An evaluation of several recently available verifiers is discussed in this paper. Operating environments and procedures more typical of physical access control use can reveal performance substantially different from the basic laboratory tests. (Author abstract)

**077212 PREPARING THE SECTION FOREMAN FOR HIS FULL RESPONSIBILITIES.** The health and safety of employees, efficiency of the operating systems, and production are paramount goals in underground coal mining. The section foreman assumes responsibility for making his part of the total system function to meet these goals. However, section foremen often have not been prepared to assume the full range of their responsibilities upon becoming a supervisor. This paper addresses the full range of section foreman responsibilities and concomitant authority. Management principles that must be mastered by him are presented, and performance expectations as well as criteria for their evaluation are examined. The benefits realized from effective foreman training are discussed. (Author abstract) 7 refs.

**077217 PESTICIDE FORMULATIONS AND APPLICATION SYSTEMS: FIFTH VOLUME.** This conference proceedings contains 15 papers divided into 2 sections. The first section discusses General Topics; the second session is concerned with the use of Spray Drop Size Analyzers. Some of the topics in the first section are the formulation of pesticides; metering of pesticide concentrations; electrostatic spraying; and the use of water-soluble polymer suspending agents. In section two: drop size measurement; instruments and procedures in drop-sizing; laser droplet interferometry analysis; and two-dimensional imaging spectrometry, as well as laser imaging systems, are discussed. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11002 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**Adsorption**

**077218 ADSORPTION OF THIRAM FROM AQUEOUS SOLUTION ON ACTIVATED CARBON AND SEPIOLITE.** Recently, the extent of pesticide contamination of the water environment has raised much concern because of the potential health hazards associated with the entry of these compounds into the food chain of humans and animals. One of the main reasons that decontamination and disposal of these hazardous waste chemical is such a complex problem involves the wide range of chemical compounds which are used as pesticides. It is difficult, if not impossible, to produce a single method for pesticide disposal that applies universally. Therefore, several methods for decontamination and disposal of these unwanted chemicals may be required to solve this problem. Sorption on solid substrates, such as clay or activated carbon, is one of the methods which has been used for removing pesticides from waters. This study evaluates the effectiveness of the activated carbon and an

acid-heat treated sepiolite in removing the pesticide thiram ( $C_6H_{12}N_2S_4$ ) from aqueous solution over a range of experimental conditions. 10 refs.

**077221 EFFECTS OF ELECTROSTATIC CHARGING AND VERTICAL AIR CURRENT ON DEPOSITION OF PESTICIDE ON COTTON PLANT CANOPY.** The objectives of this study were to investigate the influence of electrostatic force and vertical air current to carry pesticide deposits, obtained by cone, fan and disc type nozzles, on the cotton plant canopy. The pesticide deposit quantities and the relative deposition rates were determined and compared between different application treatments using three different nozzle types. As tracer substance BSF was used, the deposit was detected by fluorometric method. The results obtained by BSF were controlled by using real pesticide. Because of the high relative humidity during the application period, electrostatic charging effectiveness was not as high as expected. (Author abstract) 17 refs.

## Chemical Reactions

**077223 INTERACTION OF PHENAMIPHOS WITH MONTMORILLONITE.** Phenamiphos interacted with homoionic montmorillonites of  $Ca^{2+}$ ,  $Mn^{2+}$

,  $Co^{2+}$ , and  $Ni^{2+}$  to form interlayer complexes having basal spacings of about 16.5 Å. In the infrared spectra, the  $\nu$ -PO bands were displaced towards lower frequencies suggesting that this group interacted with the exchange cations. Moreover, a small shoulder at 1600  $cm^{-1}$  indicated the partial protonation of the phenamiphos. After heating the complexes to 110°, 160°, and 200°C, however, the bands corresponding to  $\delta$ -NH $_2^+$  and  $\nu$ -NH intensified because of increased protonation, whereas the  $\nu$ -PO bands had the same intensity as in pure phenamiphos. The fundamental implication of these observations is that phenamiphos interacts with exchange cations through molecules of coordinated water, possibly by means of the P=O group. (Author abstract) 13 refs.

**077224 RAPID DETERMINATION OF ORGANO-CHLORINE PESTICIDE RESIDUES IN FEEDS BY CAPILLARY GAS CHROMATOGRAPHY.** A simple micro-method is described for determination of 15 organochlorine pesticide residues in mixed feeds. Clean-up of the petroleum ether extract is by basic alumina minicolumn chromatography and quantitative identification is by capillary gas chromatography with electron capture detection. Cyano-propyl-polysiloxane chemically bonded fused silica capillary columns have been used to perform high resolution analyses in short time as well as to overcome possible interferences by PCBs. Recovery, repeatability, and detection limits of the proposed procedure are checked and results are also reported for non random samples of 180 feeds collected in Italy. (Author abstract) 9 refs.

**077225 POSTCOLUMN PHOTOLYSIS OF PESTICIDES FOR FLUOROMETRIC DETERMINATION BY HIGH-PERFORMANCE LIQUID CHROMATOGRAPHY.** A high-performance liquid chromatography postcolumn reaction detector that employs UV photolysis with an optional reaction by using o-phthalaldehyde-2-mercaptoethanol (OPA-MERC) followed by fluorescence detection was found to be useful for several classes of pesticides. In the presence of the OPA-MERC reagent, most carbamates, carbamoyl oximes, carbamothioic acids, and substituted ureas gave a sensitive response while the response of dithiocarbamates, phenylamides, and phenylcarbamates varied. The response of most of the pesticides tested was significantly affected by the solvent used. (Edited author abstract) 19 refs.

## Decomposition

**077229 PHOTODECOMPOSITION OF PICLO- RAM IN THE PRESENCE OF HYDROGEN PEROXIDE.** The present investigation is a continuation of studies of the process of decomposition of picloram (4-amino-3,5,6-trichloropicolinic acid) in aqueous media under the effect of UV light. The investigations were carried out at a concentration of picloram in the irradiated solutions of  $5 \cdot 10^{-4}$  mole/liter. The picloram may be decomposed either as a result of photolysis or due to its reaction with  $H_2O_2$  photodecomposition products. The relative role of these two basic directions of this photoreaction depends principally on the distribution of the actinic light energy absorbed by the system between the photoactive components - picloram and hydrogen peroxide. Thus, the concentration of the components was varied so that in the corresponding series of experiments the light was absorbed predominantly by only one of the reaction components. At an  $H_2O_2$  concentration of less than  $5 \cdot 10^{-3}$  M, picloram is the principal light-absorbing and, consequently, photoactive component of the investigated solutions. At higher  $H_2O_2$  concentrations its molecules also take part in the primary photochemical process. 10 refs.

**077230 LIVER WEIGHT RESPONSE TO EXTENDED CHLORDEKONE EXPOSURE.** Chlordane (Kepone) is a chlorinated hydrocarbon pesticide that

has been shown to be both a neurotoxin and a reproductive toxin. Of primary concern is whether a female, who is exposed to a chemical agent such as chlordecone in the workplace, not continuously, but for five consecutive days at a time for an extended period of time, would suffer ill effects. The purpose of this study is to determine the response of the liver to specific doses of chlordecone for five consecutive days/week for periods of up to ten weeks. An understanding of the liver response to this regimen of exposure is necessary because this timetable best reflects the occupational exposure that might occur. Study materials, methods and results are discussed. 17 refs.

**077231 LAUNDERING VARIABLES IN REMOVING CARBARYL AND ATRAZINE RESIDUES FROM CONTAMINATED FABRICS.** During mixing and application of pesticides, the clothing worn by agricultural or urban pesticide applicators is subject to contamination. Completeness of pesticide removal in laundering is essential if the garment is to be used again. This study examines the efficacy of laundering variables such as detergent type, wash water temperature and number of launderings in removal of carbaryl (1-Naphthyl-N-methyl carbamate) and atrazine (2-Chloro-4-ethylamino-6-isopropylamino-S-triazine) residues from fabrics of various fiber contents. In addition, the effect of durable-press functional finish on residue removal from polyester/cotton fabrics is examined. 17 refs.

Raheel, Mastura (Univ of Illinois, Urbana, IL, USA). *Bull Environ Contam Toxicol* v 38 n 4 Oct 1987 p 671-679.

**077232 EXPORT OF MIREX FROM LAKE ONTARIO TO THE ST. LAWRENCE ESTUARY.** The relative importance of migrating eels and suspended particulate material (biotic and abiotic) as transporters of mirex from Lake Ontario to the St. Lawrence River Estuary is evaluated in the context of a possible adverse impact on the St. Lawrence beluga population. Estimates suggest that transport of mirex out of Lake Ontario by eels (2270 g annually) is almost twice that due to suspended particulate flux (1370 g annually). Mass balance calculations for mirex in Lake Ontario indicate that transport by migrating eels and particulate matter, combined with coverage of surficial sediments by continuing deposition of new material, could effectively 'cleanse' Lake Ontario of mirex inputs in 100 years or less. Using mirex as a prototype to simulate the fate of hydrophobic organic chemicals in Lake Ontario led to a revised sediment budget for this final lake in the Great Lakes-St. Lawrence system, which the paper also discusses. (Edited author abstract) 36 refs.

**077233 EVALUATION OF PESTICIDE GROUNDWATER POLLUTION POTENTIAL FROM STANDARD INDICES OF SOIL-CHEMICAL ADSORPTION AND BIODEGRADATION.** A mathematical screening model of the pesticide leaching process is used to estimate the potential for a pesticide to reach groundwater at significant concentrations. The model assumes steady water flow, equilibrium linear adsorption, and depth-dependent first-order biodegradation and predicts groundwater travel times and residual concentrations that depend on soil and environmental conditions as well as pesticide adsorption and decay constants. When groundwater protection is expressed as a condition that the residual undegraded pesticide mass remaining below the surface layer of soil must be less than a specified fraction of the initial mass added in a pulse application at the surface, the model prediction is shown to reduce to a linear inequality between the organic C partition coefficient  $K_{oc}$  and the biochemical half-life,  $\tau$ . The screening model is illustrated on 50 pesticides and two scenarios representing low and high potential for groundwater contamination. (Edited author abstract) 24 refs.

**077234 COEFFICIENTS OF PESTICIDE ENTRAINMENT FROM DRAINAGE BASINS.** Summarized and analyzed are Soviet and foreign publications on the conditions and factors which influence the formation and character of surface runoff and pesticide entrainment from soils of agricultural lands and the modeling of entrainment of xenobiotics into surface reservoirs. Estimated are the coefficients of entrainment and the role of surface runoff from a drainage basin as factors in the pesticide pollution of water sources. (Author abstract) 25 refs.

Medovar, A.M. (All-Union Scientific Research Inst of Hygiene & Toxicology of Pesticides, Polymers, & Plastic Masses). *Sov Meteorol Hydrol* n 9 1987 p 100-103.

**077235 CHLORINATED PESTICIDES IN INDOOR AIR.** Indoor concentrations of chlorinated pesticides were measured in the air of 12 homes and found to be elevated with respect to typical outdoor concentrations. For example, indoor to outdoor concentration ratios for  $\gamma$ -chlordane were as high as 60 in the living area of one home and as high as 1000 in the basement of this home. Indoor sources for these chemicals are implied. (Author abstract) 20 refs.

**077236 BEHAVIOR OF PESTICIDES IN LAKE KASUMIGAUZA, JAPAN.** Pesticides such as oxadiazon, isoprothiolane, diazinon, IBP, simetryne and benthicarb, from surface runoff from rice paddy fields to Lake Kasumigaura, Japan were examined in order to determine seasonal changes in their concentrations in the lake water. The highest concentrations were observed near the river mouths during May to August, soon after pesticide application; hence they are transported mainly by surface runoff. Although these pesticides have been reported to be labile, concentrations of some of them, dispersed with the movement of the water, did not decrease rapidly in the natural aquatic environment. The highest concentrations, in 1985, of oxadiazon, isoprothiolane, diazinon, IBP, simetryne, benthicarb and CSB were 0.66, 0.84, 0.16, 3.24, 3.23, 2.15 and 1.13 ppb, respectively. The relative order of persistence and mobility of pesticides in the lake water was estimated as: isoprothiolane, CSB, simetryne > IBP > diazinon > oxadiazon > benthicarb. (Author abstract) 23 refs.

Shiraishi, Hiroaki (Natl Inst for Environmental Studies, Yatabe, Jpn); Pula, Flutra; Otsuki, Akira; Iwakuma, Toshio. *Sci Total Environ* v 72 Jun 15 1988 p 29-42.

**077237 PESTICIDE TRANSPORT IN SHALLOW GROUNDWATER.** Residues of selected pesticides, EDB, atrazine, butylate, aldicarb, and fenamiphos were monitored in shallow groundwater beneath a Bonifay sand in the southeast Coastal Plain near Tifton, GA. Pesticides in the tile outflow from the treated area were also monitored along with pesticide residue in soil. Low concentrations of atrazine and butylate were present in wells at depths of 1.0 m, 1.5 m, and 2.4 m beginning with the second year (1984) of the study. Fenamiphos was detected in only one well throughout the study. However, EDB and aldicarb moved readily to groundwater and in the tile outflow. Masses of pesticide transported from the treated area were computed using concentrations and estimated water budgets. Comparing leaching losses from the root zone estimated using GLEAMS simulation with groundwater transport shows that < 10% of the leaching losses were actually transported from the treated area in shallow groundwater during the observation period. (Edited author abstract). 21 Refs.

**077238 PESTICIDES IN AGRICULTURAL WATERS: THE ROLE OF WATER QUALITY GUIDELINES.** This paper focuses on the relationship between the use of pesticides in Canadian agriculture and the hazards associated with the quality of agricultural waters used in irrigation and livestock watering. The extent and complexity of this problem is assessed initially by examining the overlap between pesticide use and agricultural water use in Canada. The inherent properties of selected pesticides used in Canadian agriculture are highlighted and related to their potential for release to agricultural water supplies. Field and laboratory investigations as related to agricultural water uses are reviewed and a discussion of pesticide water quality guidelines to ensure protection of agricultural water supplies is provided. (Edited author abstract). 57 Refs.

**077239 EFFECTS OF PARAQUAT ON MICROSOMAL OXYGEN REDUCTION AND ANTIOXIDANT DEFENSES IN RIBBED MUSSELS (GEUKENSIA DEMISSA) AND WEDGE CLAMS (RANGIA CUNEATA).** In vitro studies indicated a dose-dependent increase in the rate of superoxide anion ( $O_2^-$ ) generation in microsomal fractions supplemented with NADPH; the highest concentration of paraquat employed (4mM) elicited an 81% increase in cytochrome c reduction in *G. demissa* and a 135% increase in *R. cuneata*. In both species, cytochrome c reduction was inhibited by the addition of exogenous superoxide dismutase (SOD). For in vivo studies, a single application of paraquat (0.5, 1.0 or 2.0 mM) was added to aerated salt-water aquaria containing *G. demissa*. Biochemical analyses of antioxidant enzymes, reduced glutathione (GSH) and lipid peroxidation were performed in hepatopancreatic tissue after exposures of 6, 12, 24 and 36 h. (Edited author abstract) 11 refs.

## Fires

**077240 PREINCIDENT PLANNING FOR PESTICIDE FIRES.** A recognized procedure (evolved through preincident planning and fire scene size-up) for a pesticide storage fire is to let it burn. If the structural fire temperature can be raised to more than 1,800°F, thermal decomposition of the pesticides into less toxic products can be effected. The structure should be vented as much as possible so the fire can proceed in the free-burn stage. In deciding on a let-it-burn strategy, three factors of chemical destruction by combustion are considered: temperature, time and turbulence.

Bowen, John E. (Prince George's County Fire Dep, MD, USA). *Fire Eng* v 141 n 2 Feb 1988 p 36-39.

## Leaching

**077241 CHARACTERIZING THE UNCERTAINTY OF PESTICIDE LEACHING IN AGRICULTURAL SOILS.** A Monte-Carlo numerical simulation procedure for making regional assessments of pesticide leaching has been developed. This procedure uses probability density functions for organic matter, field capacity, and wilting point developed from information on approximately 3000 soils. Variations in climatic conditions were incorporated by random selection of yearly rainfall data. The procedure was demonstrated for aldicarb applied to corn grown in Ohio. A total of 2000 parameter sets were evaluated using the unsaturated zone model PRZM. The simulation results indicated that convergence of the 90th, 95th, and 99th percentiles for movement past 0.3, 0.6, 0.9, and 1.5 m was obtained after 500 simulations. The relative uncertainty associated with these percentiles was approximately 50% after 1500 simulations. The downward movement of aldicarb residues was most sensitive to changes in field capacity. These simulations, coupled with additional

soil-specific simulations, indicated no significant movement of aldicarb residues beyond 1.8 m for applications to Ohio corn. (Author abstract) 31 refs.

Carsel, Robert F. (US EPA, Athens, GA, USA); Parrish, Rudolph S.; Jones, Russell L.; Hansen, James L.; Lamb, Richard L. *J Contam Hydrol* v 2 n 2 Mar 1988 p 111-124.

**077242 SIMULATION PROCEDURE FOR GROUNDWATER QUALITY ASSESSMENTS OF PESTICIDES.** A procedure is described for making regional assessments of pesticide residue loadings and movement in groundwater underneath and downgradient from treated fields. A Monte-Carlo numerical simulation technique is used to generate model parameters for both the unsaturated and saturated zones. Simulations are performed using the Pesticide Root Zone Model linked to a simple groundwater solute transport model. The procedure is useful for evaluating the potential for producing pesticide residues in drinking water wells before actual field applications are made. Appropriate land management options, including restrictions on pesticide application, also can be developed using this procedure. The procedure was used to assess aldicarb levels in northeastern North Carolina groundwater resulting from application of the pesticide to peanuts. Probability density functions for selected soil characteristics were developed using a direct-access soils information data base. Probability density functions for selected groundwater characteristics were developed from available data for the study area. Simulation results indicated that mass fluxes to groundwater exceeded 0.01 and 0.1 kg ha<sup>-1</sup> approximately 6.9 and 1.0 percent of the time, respectively. No fluxes exceeded 0.1 kg ha<sup>-1</sup> at a distance of 60 m downgradient in any of the cases evaluated. (Author abstract) 24 refs.

Carsel, Robert F. (EPA, Athens, GA, USA); Jones, Russell L.; Hansen, James L.; Lamb, Richard L.; Anderson, Mary P. *J Contam Hydrol* v 2 n 2 Mar 1988 p 125-138.

## Manufacture

**077243 STATE OF IMMUNITY IN THOSE OCCUPATIONALLY EXPOSED TO PESTICIDES.** The state of immunity in those having a long-term contact with pesticides, i.e., mechanics and storehouse workers, is examined. Unbalance of immunologic indicators detected in T-cell subpopulations is specified by an increase in the number of inducers and decrease in the level of immunogenesis regulators. The studied immunity disfunction directly depends on the length of service. Weakening of the inhibition mechanism of T-suppressors due to their quantitative decrease results in hyperproduction of general immunoglobulin E. A high level of spontaneous proliferation of lymph cells indicates endogenous T-cell stimulation. Immunity disfunction is accomplished by an increase in the incidence of pathologic changes of the cardiovascular, nervous, and digestive systems. (Author abstract) 17 refs. In Russian.

## Modification

**077244 POLYMER-MODIFIED MICROELECTRODES FOR METAL ION DETERMINATION AND THE DEVELOPMENT OF A CALCIUM AMPEROMETRIC PROBE BASED ON SURFACE-IMMOBILIZED ANTIPYRYLAZO III.** The feasibility of employing chemically modified microelectrodes in analytical determination is demonstrated. For Fe(II), determinations down to  $5 \times 10^{-8}$  M could be performed, and this limit was dictated by background levels of Fe(II) rather than by the sensitivity of the method. In addition, the utility of electrodes modified with antipyrilazo III (AP-III) for the determination of Ca<sup>2+</sup> is shown. These electrodes exhibit submicromolar sensitivity and a dynamic range that extends over 3 orders of magnitude. The presence of magnesium at a thousand-fold excess has only minor effects. (Edited author abstract) 45 refs.

Hurrell, Helen C. (Cornell Univ, Ithaca, NY, USA); Abruna, Hector D. *Anal Chem* v 60 n 3 Feb 1 1988 p 254-258.

## Oxidation

**077245 OXIDATIVE DESTRUCTION OF UREA DERIVATIVE PESTICIDES.** Pesticides of the phenyl-substituted-urea type have been used extensively in agriculture and pose a problem for water pollution. Chlorine and ozone were employed in an experiment to oxidize the above pesticides found in water. The investigation permitted a comparison of the prospects for ozone with those for a reagent (chlorine) widely used in water treatment practice, with an indication of the limits of applicability of these oxidizers. It was shown that for treatment of phenyl-substituted ureas active chlorine or preparations containing it should be used only on waste waters. In distinction from chlorine, ozonation is applicable both in processes of preparation of potable water and in the treatment of waste waters. The choice of the oxidizer - chlorine or ozone - in the treatment of waste water is dictated by the particular water composition. 15 refs.

Konyk, L.V. (Dumanskii Inst of Colloidal Chemistry & Water Chemistry, Kiev, USSR); Taran, P.N.; Shevchenko, M.A. *Sov J Water Chem Technol* v 9 n 2 1987 p 67-70.

## Removal

**077246 REMOVAL OF TETRAMETHYL THIURAM DISULPHIDE FROM AQUEOUS SOLUTION BY CHEMICALLY MODIFIED BENTONITE.** The adsorption of tetramethyl thiuram disulphide (thiram) on bentonite, acid-treated with H<sub>2</sub>SO<sub>4</sub> (over a concentration range between 0.25 mol dm<sup>-3</sup> and 2.00 mol dm<sup>-3</sup>), and heat-treated at 110°C or at 200°C, from aqueous solution at 20°C has been studied. In general, the adsorption isotherms may be classified as L type of the Giles classification which suggests that there is no strong competition from the solvent for adsorption sites. The experimental data points have been fitted to the Freundlich equation in order to calculate the adsorption capacities (K) of the samples; K values range from 230 µg g<sup>-1</sup> for the sample acid-treated with 0.25 mol dm<sup>-3</sup> H<sub>2</sub>SO<sub>4</sub> and heat-treated at 110°C up to 2010 µg g<sup>-1</sup> for the sample acid-treated with 1.00 mol dm<sup>-3</sup> H<sub>2</sub>SO<sub>4</sub> and heat-treated at 200°C. In all cases the K values for samples heat-treated at 200°C were higher than those heat-treated at 110°C. The removal efficiency (R) has also been calculated for all the samples; R values range from 42.8 percent up to 89.9 percent. (Author abstract) 17 refs.

Gonzalez Pradas, E. (Colegio Univ de Almeria, Almeria, Spain); Villafraña Sanches, M.; Valverde Garcia, A.; del Rey Bueno, F.; Garcia Rodriguez, A. *J Chem Technol Biotechnol* v 42 n 2 1988 p 105-112.

**077247 FILTERING UNIT FOR THE REMOVAL OF PESTICIDE RESIDUES FROM AQUEOUS SOLUTIONS.** Pesticide loss during filling and washing spray tanks can be considerable especially where cooperative pesticide distribution centers exist (up to 200 1000-liter tanks daily). A filtering unit using readily available organic media (peat, moss and manure) was designed to filter out a variety of commonly-used pesticides in apple orchards. Each filtering unit received residues from 20 pesticide applications consisting of a typical pesticide treatment schedule for apples. Initial concentration of the pesticides in the wastewater was between 26 and 1820 mg l<sup>-1</sup>. Average removal efficiencies were > 99 percent for dodine, copper oxychloride, azinphos methyl, triadimefon, bifenox, dithianon, fenarimol, chlorpyrifos ethyl, cyhexatin, benzoate, dinocap and benomyl. Removal efficiency for vamidothion averaged 61 percent; removal for sulphur was 73 percent. Bioassays with *Daphnia magna* and *Gloeosporium* sp. were performed to evaluate effluent toxicity. (Author abstract) 6 refs.

**077248 DIRECT OBSERVATION OF PESTICIDES ON PLANTS USING LAMMS: IMAZAQUIN ON SOYBEAN LEAVES.** LAMMS (Laser Microprobe Mass Spectrometry) has been used to observe the presence and location of a herbicide on plant leaves. Leaves from soybean plants, sprayed with imazaquin, a member of the imidazolinone class of herbicides, at varying application rates, were examined by LAMMS without any special preparation. A rapid analysis for imazaquin was obtained confirming the suitability of LAMMS as an organic microprobe analyzer. A comparison with standard chemical ionization and electron impact mass spectra of imazaquin showed evidence for laser-induced fragmentation. (Author abstract) 4 Refs.

**077252 INCENTIVES IN PRODUCTION: A CASE STUDY.** The motivation, rationale, and experiences of implementing an incentive scheme in a large petrochemical plant in the People's Republic of China for the purpose of conserving the consumption of cooling water is described. Experimental implementation in a section of a plant is described in detail. A few incentive-induced features uncovered after analyzing the experimental data are reported. A mathematical model with several variations is presented. A better predictive property of the incentive scheme in comparison to a more conventional method is proved analytically. The effectiveness of the scheme is shown by the amount of water conserved, and by the management's decision for plantwide adoption of the scheme. Practical issues encountered in experimental implementation, extensions of the scheme to more general situations, and theoretical problems inspired by the

experiment are discussed. 8 refs.

## Effluent Treatment

**077256 NITROGEN AND PHOSPHATE REQUIREMENTS FOR THE ANAEROBIC DIGESTION OF A PETROCHEMICAL EFFLUENT.** This study was undertaken to determine the minimum nitrogen and phosphate concentrations at which the downflow fixed-bed anaerobic reactor could still operate efficiently. Results obtained from the first phase of the study showed that urea could be successfully substituted by ammonia, when the reactor population became acclimatized to the newly added nitrogen source. In the second phase it was found that the substrate phosphate concentration necessary for efficient reactor performance, could be lowered from 115 to 8 mg l<sup>-1</sup> as PO<sub>4</sub>-P. At this level no phosphate could be detected in the reactor effluent. In the final phase the substrate ammonia concentration necessary was lowered from 1060 to 45 mg l<sup>-1</sup> TKN. At these low phosphate and nitrogen concentrations, the reactor was still able to operate at COD (Chemical Oxygen Demand) removal efficiency > 95%. (Author abstract) 30 refs.

Britz, T.J. (Univ of the Orange Free State, Bloemfontein, S Afr); Noeth, C.; Lategan, P.M. *Water Res* v 22 n 2 Feb 1988 p 163-169.

**077257 SIDESTREAM SOFTENING SYSTEM CUTS PETROCHEM PLANT'S EFFLUENT.** USS

Chemical's Houston plant produces ethylene from an ethane rich refinery gas by steam cracking. Prior to 1979, the plant discharged roughly 300 to 500 gpm of effluent to the Houston Ship Channel. The construction of a maximum recycle sidestream softening system began in 1977 for the treatment of wastewater from the plant. The system is composed of two lime softening units that treat the blowdown from the cooling water system. The softeners remove the calcium, magnesium, silica, and carbonate ions. Softened water is processed through a recarbonator and filter for return to the cooling water system. Carbon dioxide is used to control pH in the cooling water system instead of sulfuric acid. Polymaleic anhydride polymers mechanistically prevented scale formation by fluidizing small crystals rather than inhibiting crystals rather than inhibiting crystal formation.

Matson, Jack V. (Univ of Houston, Houston, TX, USA); Mouche, Wendy G.; Rosenblum, Eric. *Oil Gas J* v 83 n 20 May 20 1985 p 76-78.

## Electric Equipment

**077258 PRINCIPALES CARACTERIQUES, CONCEPTION ET EVOLUTION DES ENTRAÎNEMENTS ELECTRIQUES DESTINES AU REMPLACEMENT DE TURBINES DANS L'INDUSTRIE CHIMIQUE.** [Main Features, Design Requirements and Development of Electric Motors Drives Fitted to the Replacement of Steam Turbines in Chemical Plants]. During the last few years French petrochemical and refining plants have replaced a comparatively important amount of steam turbines by electric motor drives. This paper gathers data regarding the solutions which seem to be the more suitable in this matter, thereby directed to powers being above 1MW. Limits of feasibility and characteristics of constant speed drives are given. The subject of variable speed drives is then tackled with a special stress on the principle, the performances and the selection and design criteria of the most used solutions which are currently: the design criteria of motor with hydrodynamic coupling and mainly the synchronous motor fed by frequency converter. The constraints that have to be taken into consideration before connecting the various types of drives are explained. The interest in high power electric motor developments to increase the available speeds is emphasized. (Edited author abstract) In French. 11 refs.

## Environmental Impact

**077260 COMMUNITY ODOURS IN THE VICINITY OF A PETROCHEMICAL INDUSTRIAL COMPLEX.** Community odors in the vicinity of an oil refinery and petrochemical industrial area were studied by an observer network throughout an entire year. Odor episodes occurred during 0.86 percent of the time of the study. Odor reports increased closer to the refinery. Within a range of 12.5 km, more than 50 percent of the odors were estimated to originate from the refinery. The most typical odor was that of reduced sulfur compounds (35.2 percent of all observations). Odor episodes occurred during low wind velocities and high humidity. Odors were most frequent during January-April, and were usually reported early in the morning. The odors were evidently due to the general operation of the plants, as no single activity or in-plant factor could be identified as the source

of the odors. (Author abstract) 15 refs.

Persson, Per-Edvin (Finnish Science Cent Foundation, Vantaa, Finl); Skog, Stefan; Hasenson, Benny. *JAPCA* v 37 n 12 Dec 1987 p 1418-1420.

**077261 ENVIRONMENTAL CONSIDERATIONS IN PLANNING PETROCHEMICAL COMPLEXES - A CASE STUDY FOR THE PROPOSED COMPLEX AT SALEEMPUR, U.P.** An in-depth study was conducted on extent and quality of a green belt and the manner in which the same could be achieved most effectively. Keeping in mind the constraints imposed by locality factors, such as alkaline soil, waterlogging etc., as also the impact of the proposed petrochemical complex, a strategy for establishment of a green belt is being evolved. This paper describes the considerations of the choice of species, planting techniques and manner in which the green belt needs to be maintained. Such an approach will ensure development with the least ecological disturbance i.e., development without destruction. (Edited author abstract) 23 refs.

**Retrofitting** See PETROLEUM REFINERIES—Retrofitting.

## Saudi Arabia

**077263 GENERAL ENVIRONMENTAL PLANNING AND MANAGEMENT OF A PETROCHEMICAL COMPLEX IN SAUDI ARABIA - A CASE STUDY.** This paper examines the general environmental planning and management considerations that were involved in the design of a petroleum refinery to be located in the Qasim area of the Kingdom of Saudi Arabia. We present details of the considerations that were involved in the environmental planning of the Qasim refinery and provide specific information on the control of the refinery's air, water, noise, solid and hazardous waste streams. Even though this particular project did not proceed to completion, it does provide an excellent case study of the environmental planning and management activities that are currently being practiced to protect the environment in Saudi Arabia. In conclusion, had the project proceeded to completion, it would have resulted in a modern refinery operating without any significant adverse environmental impacts and with the maintenance of a clean and safe environment for adjacent communities. 7 refs.

## Economics See Also PETROLEUM GAS, LIQUEFIED.

**077268 RISING COSTS PREDICTED FOR WORLD PETROCHEMICAL RAW MATERIALS.** Since the subject of world petrochemical raw materials is so vast, a great deal of selectivity is exercised to present a brief outlook. The first selection made is to limit this paper to hydrocarbons. The hydrocarbons reviewed fall into three basic categories. The lightest is methane, or natural gas, which is used to make methanol and ammonia. Next come the natural gas liquids and LPGs. The natural gas liquids are comprised specifically of ethane, propane, isobutane and normal butane. The next category is the dominant source of petrochemical manufacture: naphtha.

Acosta, T. (DeWitt & Co, Houston, TX, USA). *Hydrocarbon Process* v 67 n 2 Feb 1988 p 90A-90B, 90E, 90G-90H.

**077269 WORLD-SCALE MODEL PREDICTS PETROCHEMICAL TRENDS.** The petrochemicals industry is in the midst of a global structural change caused by the ability of energy-rich industrially developing nations to undercut the prices of bulk chemicals traditionally produced by the United States, Western Europe and Japan. The maturing of the industry and saturation of the markets is causing a shift in the advantages in production

away from innovations in process technology towards the availability of cheap feedstocks. Countries with a great abundance of cheap petroleum and natural gas are beginning to export not only these basic resources but also the more valuable petrochemical derivatives. Often the new petrochemical producers are far from the traditional markets and are subject to restraints imposed to protect those markets. Also, it is usually more expensive to build the manufacturing facilities in an industrially undeveloped nation to compete with facilities that already exist elsewhere.

Sigurdsson, M. (Univ of Wisconsin, Madison, WI, USA); Rudd, D.F. *Hydrocarbon Process* v 67 n 6 Jun 1988 p 98.b-98.n.

**077270 WORLD-SCALE MODEL PREDICTS PETROCHEMICAL TRENDS.** A model is used to examine the advantage of the petroleum-rich regions in the established markets of the United States, Western Europe and Japan. The regions considered are Canada, Mexico, Middle East, Africa and Australasia. There are three questions that a model of international trade should be able to answer: What chemicals do countries trade? With whom do countries trade? How much do countries trade? To evaluate the competitiveness of the products from those five regions in the developed world, the model is run under restricted trade environment; that is, a small upper bound is placed on all trade activity and the magnitudes of the penalty terms observed. 2 Refs.

## Physical Properties

**077271 DEGREE OF DRYING AND CORROSIVITY OF PETROLEUM SULFOXIDES.** The authors establish the sources of formation of sludge during prolonged storage of sulfoxides in St3 mild steel drums, and evaluate the quality of the sulfoxides after extended storage. Experimental data indicate that extended storage of the sulfoxides over a period of 1.5 years in a St3 steel drum does not affect the sulfoxide quality. But in the presence of water, the sulfoxides become contaminated with corrosion products. This means that if the sulfoxides are to be stored for extended periods or transported, either they must be dried (part of the dissolved water must be removed) or alloy steel drums must be used. In order to determine the required degree of drying of the sulfoxides corrosion tests were run on metals in a laboratory unit under static conditions at room temperature. In rating the test results, the basic index of the rate of uniform corrosion was the ratio of specimen weight change per unit of surface area per unit of time. In order to characterize the scatter of the data, average values of the corrosion rate were taken from tests on three specimens of the same steel.

## Production

**077272 CATALYSEURS ET PROCEDES CATALYTIQUES UTILISES DANS LA PRODUCTION DES GRANDS INTERMEDIAIRES PETROCHIMIQUES: SITUATION ACTUELLE ET FUTUR.** [Catalysis and Catalytic Processes Used for the Production of the Major Petrochemical Building Blocks: Present Situation and the Future]. Petrochemicals account for a modest share of the market for catalysts, but there have been substantial improvements in the catalysts and processes used in the last ten years. These improvements have brought about a better response to the demand for major petrochemical building blocks. This trend is clearly

illustrated by hydrogenations in the field of steam cracking to produce olefins, by catalytic reforming and satellite processes to produce aromatics, and by new processes such as dehydrogenation, metathesis and oligomerization which provide better balance to the market for olefins. **077273 POSSIBLE LATE MIDDLE ORDOVICIAN ORGANIC CARBON ISOTOPE EXCURSION: EVIDENCE FROM ORDOVICIAN OILS AND HYDROCARBON SOURCE ROCKS, MID-CONTINENT AND EAST-CENTRAL UNITED STATES.** Oils generated by Middle Ordovician rocks are found throughout the Mid-Continent and east-central regions of the United States. Gas chromatographic characteristics of these oils include a relatively high abundance of n-alkanes with carbon numbers less than 20, a strong predominance of odd-numbered n-alkanes between C<sub>10</sub> and C<sub>20</sub>, and relatively small amounts of branched and cyclic alkanes. The wide ranges in  $\delta^{13}\text{C}$  for oils and rock extracts reflect a major, positive excursion(s) in organic matter  $\delta^{13}\text{C}$  in late Middle Ordovician rocks. This excursion has at least regional significance in that it can be documented in sections 480 mi apart in south-central Kansas and eastern Iowa. The distance may be as much as 930 mi. The parallel shifts in organic and carbonate  $\delta^{13}\text{C}$  in core samples from 1 E.M. Greene well, Washington County, Iowa, imply changes in the isotope composition of the ocean-atmosphere carbon reservoir. These and other aspects of the subject are discussed. (Edited author abstract) 60 refs.

**077274 MACROSTRUCTURE OF ASPHALTENE DISPERSIONS BY SMALL-ANGLE X-RAY SCATTERING.** Three asphaltene dispersions have been studied by small angle X-ray scattering. Pematang and Grenada are two benzene dispersions of asphaltenes from atmospheric residues (350°C). Safaniya is asphaltene dispersed in maltene from a vacuum residue. The scattering data present characteristic profiles which can be explained by comparing the experimental with simulated curves. The macrostructure model used for the curve simulations is based upon a distribution of thin discs which all have the same thickness (3.4 Å) and a radius which follows a power law. The validity of such a model, discussed in the light of known properties of the asphaltenic particles, suggests that these membranes could result from the aggregation of small Yen's elementary units. (Edited author abstract) 30 refs.

**077275 PRESENCE OF TRACE ELEMENTS IN CRUDE OILS AND ALLIED SUBSTANCES.** Individual crude oils have distinct trace element patterns, apart from what may be termed the common bulk earth elements. Analytical methods can now detect elements down to parts per billion. The distinction in the content of trace elements can be employed, as finger prints, to identify the source of an unknown crude specimen - as in an oil spill accident. While some of the elements found in crudes appear to be extrinsic in nature, some appear to be

intrinsic; that is to say, they may be part of the fossil organic matter not derived from the geologic surroundings. 7 refs.

Jones, Peter (Inst of Petroleum, London, Engl). *Pet Rev* v 42 n 497 Jun 1988 p 39-42.

**077276 IDENTIFICATION OF WEATHERED OILS.** Crude oils from the Cook and Brent formations in the same well at the Gullfaks field in the North Sea were weathered for one year under natural conditions. Samples of the oils were collected at intervals and analysed by GC-MS for the common so-called biomarkers: steranes at m/z 217, and pentacyclic triterpanes at m/z 191 and m/z 177. The resulting fragmentograms were treated by multivariate analysis. The patterns of steranes differed between the unweathered oils, but weathering affected them in such a way that identification was impossible after 4 months. The pattern of pentacyclic triterpanes were different for the two oils during the year, rendering these a good tool for identification of weathered oils, the demethylated triterpanes in particular. (Author abstract). 18 Refs.

## Chromatographic Analysis

**077277 LA GASCROMATOGRAFIA NELLA GEOCHIMICA DEL PETROLIO.** [Gas Chromatography in Petroleum Geochemistry]. The aim of this paper is to describe the application of high-resolution gas chromatography (HRGC) to the geochemical study of oils and rock-extracts for oil-oil and oil-source rock correlation purposes. Certain gas-chromatographically derived parameters relevant to the type of organic matter and the depositional environment from which the oils have been generated are defined. Finally, some examples of maturity parameters and oil-oil and oil-source rock correlations are given. (Edited author abstract) In Italian.

**077278 SEPARATION AND IDENTIFICATION OF A NEW BIOLOGICAL MARKER, 18 $\beta$ (H)OLEANANE, IN CRUDE OIL AND ANCIENT SEDIMENTS, BY HIGH RESOLUTION GAS CHROMATOGRAPHY-MASS SPECTROMETRY.** One method for the analysis of complex mixtures from geological sources is the use of high resolution gas chromatography data together with mass spectra obtained by combined gas chromatography-mass spectrometry (GC-MS). The aim of this study is to separate and identify a compound that was already shown by several authors and called 'peak J', which under the usual conditions of routine gas chromatography co-elutes with the 18 $\alpha$ (H)oleanane peak. It is possible to separate the 18 $\alpha$ (H)oleanane peak and that of the 'J compound' by using commercial standard columns and the temperature program. This separation is obtained with an analysis time typical of routine analysis. The 'peak J' was identified as 18 $\beta$ (H)oleanane by mass spectrometry, using the spectra obtained as indicated above, and by retention time, co-injecting the pure compound. (Edited author abstract) 11 refs.

Caccialanza, P.G. (Agip Spa, San Donato Milanese, Italy); Riva, A. *Riv Combust* v 42 n 1 Jan 1988 p 3-8.

**077279 18 $\beta$ (H)OLEANANE IN CRUDES AND IN TERTIARY-UPPER CRETACEOUS SEDIMENTS. DEFINITION OF A NEW MATURITY PARAMETER.** Ekweozor (1979) first discovered a new unknown compound with a retention time very close to the 18 $\alpha$ (H)oleanane peak in oils and Tertiary sediments of the Nigerian Delta. This compound was called the 'J compound'. Several Authors (e.g. BENSCHAW et al. 1981, SCHOELL et al. 1981, etc.) found the 18 $\alpha$ (H)oleanane without underlining the presence of the 'J compound', because of their perfect co-elution. In this study the presence of 'J compound' has been confirmed in more than 150 rock-extracts and 20 oils from different countries, and

is identified as the 18 $\beta$ (H)oleanane by means of retention time, mass spectra and standard co-injection. Apart from Tertiary sediments, the 18 $\alpha$ (H) and 18 $\beta$ (H)oleananes have also been found in Upper Cretaceous sediments, extending the occurrence of these compounds back in age. (Edited author abstract) 11 refs.

**077280 IDENTIFICATION OF SOME NOVEL TETRACYCLIC DITERPENE HYDROCARBONS IN PETROLEUM.** A new group of tetracyclic diterpene hydrocarbons of molecular formula C<sub>19</sub>H<sub>32</sub> has been found in the Jurassic oils and condensates of the Central Kara-Kum (Turkmenia, USSR). The structure of the hydrocarbons has been determined by gas chromatography-mass spectrometry and <sup>1</sup>H and <sup>13</sup>C NMR. Of the compounds identified 4,8-dimethyl-13-isopropyltetracyclo[6.6.0.0<sup>1,11</sup>.0<sup>0,7</sup>]- and 5,14-dimethyl-10-isopropyltetracyclo[6.4.1.1<sup>1,9</sup>.0<sup>4,13</sup>]tetradeccanes are present in the highest concentrations. Some ideas are put forward about the source and the reactions involved in the formation of the hydrocarbons under natural conditions by the enzymic C<sub>5</sub> cyclization of aliphatic isoprenoids. (Author abstract). 20 Refs.

## Sampling

**077281 ROBOTISATION OF SAMPLE PREPARATION IN A PETROLEUM LABORATORY.** The Esso Research Centre near Abingdon in Oxfordshire is the main focus of research effort in Europe for the Exxon Corporation. A study of the testing carried out by the instrumental elemental analysis group showed that although many different types of analyses were carried out, 5 principal tests accounted for some 50 per cent of the workload. It was clear that big benefits would accrue from the automation of these 5 tests. The overall impression at Esso Research of the laboratory automation system employed is favorable. It has demonstrated that it is capable of carrying out the work for which it was purchased and can be left to run unattended both during the day and, when required, overnight.

**077283 PRESENCE OF TRACE ELEMENTS IN CRUDE OILS AND ALLIED SUBSTANCES.** From time to time there is an expressed interest in the trace elements' and in particular metallic elements that, measured in parts per million, are present in all crude oils. Because the pattern of many of these trace elements is quite distinctive for various crude oils, their measurement can be used, in the forensic sense, for finger printing the source of otherwise unknown oil spill found on the sea, or stranded on a coastline. Another factor of interest is that in the process of refining the crude oil, the trace metals are accumulated in the distillation residues from the crude oil. The paper reviews: what effect do they have on the fouling and possible poisoning of the catalyst and its useful life what is the effect of these trace elements when the residues are blended up to produce the heavy industrial burner fuels. 7 Refs.

**077284 METAL COMPLEXES IN FOSSIL FUELS: GEOCHEMISTRY, CHARACTERIZATION, AND PROCESSING (DEVELOPED FROM A SYMPOSIUM AT THE 191ST MEETING OF ACS).** This conference proceedings contains 26 papers. The papers are divided into the following groups: Geochemistry; processing; and Characterization. The emphasis is mostly on metalloporphyrins because these compounds possess spectral characteristics that permit detection in small concentrations and have chemical properties that allow purification from background materials. The investigations concern the compounds derived as a consequence of geochemical processes. The metal complexes formed may cause problems in processing, therefore a number of papers represent research to remove them or otherwise deal with their deleterious effects. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11463 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

## Chromatographic Analysis

**077285 DETERMINATION AUTOMATIQUE DE L'INDICE D'OCTANE ET DE LA COMPOSITION DES REFORMATS PAR CHROMATOGRAPHIE EN PHASE GAZEUSE.** [Automatic Determination of Reformate Octane Number and Composition by Gas Chromatography]. This article describes the operating conditions of an optimized chromatographic method for reformates with a view to obtaining calculated values of the research octane number (RON) different by at least one point from the values measured with a CFR engine according to the ASTM/D2699 standard. Chromatographic analysis was formed in a capillary column operating with programmed temperature. Data processing was done with a software ensuring the identification of the constituents and computing of the octane number from standard chromatographic data (retention time and peak area). The results concern some 60 different reformates. (Edited author abstract) 10 refs. In French.

## Geochemistry

**077286 COMPOSITIONAL AND GEOCHEMICAL CHARACTERISTICS OF CONTINENTAL HEAVY**

**OILS OF CHINA.** Using the solvent extraction, TLC, HPLC, GC-MS, FT-IR, UV-Visible spectrophotometry, this article analyzes the group composition, the steranes and terpanes, porphyrins, and the functional groups of asphaltene and resin components in the heavy crude oil fields of Kalamai, Uho, Dagang, Liaohe, and Jiangnan in China, and the trace metal elements in the ashes of crude of Jiangnan gypsum-salt basin. From the analyzed results, the following can be concluded: The asphaltene contents in heavy crude are 1 to 4 times higher than those in normal crude. The steranes and terpanes in the saturated hydrocarbons have two typical characteristics. Heavy oils generally contain porphyrin compounds. Their contents and types vary with the stage of the crude's maturation. The ashes of Jiangnan heavy oils contained more than 13 trace metallic elements. (Edited author abstract) 8 refs.

**077287 OIL PROSPECTS OF THE GULF OF SUEZ, EGYPT - A CASE STUDY.** Four groups of rocks, having more than 0.5 PERCENT of organic carbon are defined within the subsurface section of Rahmi area, Gulf of Suez. The deduced types of indigenous kerogen are: algal-amorphous, inertinite-woody, and herbaceous. The algal-amorphous kerogen of Rudeis/Nukhul Formations (Lower Miocene), Eocene and pre-Eocene rocks is recognized as being oil prone, that is having high capacity for generating oil. The application of hydrocarbon liquid window concept shows that the LOM values fall within the range from 8.6 to 10.8, and the thermal alteration index for the different units is not extended into oil generation window, where it ranges from immature (Kareem Formation-Lower Miocene), to moderately mature (Paleocene), to the beginning of the thermal phase of oil generation (Senonian). The vitrinite reflectance values indicate a low level of thermal maturity. The study of organic richness, quality and maturity revealed that, where the Nukhul, Eocene and Senonian rocks are buried deeper would have been excellent source rocks for oil. (Edited author abstract). 26 Refs.

Elzarka, M.H. (Alexandria Univ, Alexandria, Egypt); Mostafa, A.R. *Org Geochem* v 12 n 2 1988 p 109-121.

**077288 GEOCHEMICAL APPLICATION OF STERANE AND TRITERPANE BIOMARKERS TO A DESCRIPTION OF OILS FROM THE TARANAKI BASIN IN NEW ZEALAND.** The distributions of sterane and terpane biomarkers in a suite of 25 oils from onshore and offshore regions of the Taranaki Basin of New Zealand have been determined by gc-ms. Features of these distributions include the presence of relatively high concentrations of a number of  $C_{24}$  tetracyclic terpanes, the virtual absence of tricyclic terpanes, a predominance of  $C_{29}$  normal-, iso- and diasteranes and the presence of a number of non-hopanoid triterpanes. Based upon the distributions of  $18\alpha$ (H)oleanane, the McKee and Moturoa families of oils can be delineated. These terpane distributions are qualitatively similar to those encountered in crude oils from a number of Far-Eastern basins and from the Handil field of the Mahakam delta (Indonesia). The Taranaki oils are of approximately the same thermal maturity. An attempt has been made to correlate the McKee-1 and Maui-4 crude oils with potential source rocks from depths of 3708 m and 3825 m respectively. The rocks studied have attained insufficient maturity to have been the sources of these oils. (Edited author abstract). 43 Refs.

**077289 INVESTIGATION ON THE EFFECTS OF ORGANIC SOLVENT EXTRACTION ON WHOLE-ROCK PYROLYSIS: MULTIPLE-LOBED AND SYMMETRICAL  $P_2$  PEAKS.** Pyrolysis techniques provide an estimate of oil-generating potential of a sediment based on the amount of  $P_2$  (or  $S_2$ ) hydrocarbons. Multiple-lobed and symmetrical  $P_2$  peaks were studied to determine if extractable bitumen affected the  $P_2$  results.

Samples from the Tiglukpak and Ledbetter wells were analyzed as whole, unextracted, ground sediment and after organic solvent extraction using pyrolysis techniques. Results indicate that  $P_2$  for the Tiglukpak well appears unaffected by solvent extraction.  $P_2$  peaks for the Ledbetter well samples appear to include extractable bitumen or asphaltene. Pyrolysis-gas chromatography (pyrolysis-GC) and pyrolysis-gas chromatography-mass spectrometry (pyrolysis-GC/MS) determined the composition of the portion of the  $P_2$  peak for the Ledbetter well that was removed by organic solvent extraction. Pyrolysis-GC analysis also demonstrated that for the Ledbetter well gas-generating organic material was not removed by organic solvents. (Author abstract). 20 Refs.

**077290 ORGANIC GEOCHEMICAL CORRELATION OF OKLAHOMA CRUDE OILS USING R- AND Q-MODE FACTOR ANALYSIS.** For the past several decades, there has been a significant amount of crude oil exploration and production throughout the state of Oklahoma. Publications with respect to biological marker compound distributions and stable isotopic compositions of Oklahoma crude oils, their potential genetic relationships and possible sources have, however, been very limited. In this study, a detailed organic geochemical investigation of 46 crude oils from throughout the state of Oklahoma is presented. In addition to assessing similarities and differences of the oils with respect to reservoir ages and geologic provinces, an attempt was made to establish possible genetic relationships on the basis of combined R- and Q-mode factor analysis of source-related geochemical parameters. While the oils from throughout the state were found to be remarkably similar in chemical and stable isotopic composition, four genetic families of oils have been delineated based on this statistical approach. (Edited author abstract). 52 Refs.

**PETROLEUM COKE** See Also CHEMICAL REACTIONS—Desulfurization.

**077291 FORMATION OF PETROLEUM CARBO- NACEOUS SUBSTANCES AND THEIR INTERAC- TION WITH A METAL SURFACE.** The results are given of an investigation of the laws of interaction of carbonaceous substances with a metal surface. A mechanism of the interaction is suggested which is illustrated by experimental results. (Author abstract) 5 refs.

Kuzev, I.R.; Khairudinov, I.R.; Abyzgil'din, Yu.M. *Solid Fuel Chem* v 21 n 2 1987 p 136-138.

**077292 COKE FORMATION ON METAL FOILS FROM HEAVY OILS.** The coke deposition on nickel and steel foils during pyrolysis of heavy oils has been studied. The amount of coke deposited on the foils was found to be dependent on foil type, reactor history, feed type and reaction conditions. On nickel, an asphaltene-containing feed gave more coke than an asphaltene-free feed. The coking on the metal foils increased in the order SS-302 < Inconel 718, Inconel X < Nickel. Introducing a rougher surface by rubbing the foils increased the coking. Scanning electron micrographs of the coked foils are presented and reveal details of two types of deposit. (Edited author abstract) 23 refs.

**077293 EFECTOS DE LA ADICION DE COQUE DE PETROLEO A MEZCLAS CON PROPIEDADES PLASTICAS DIFERENTES.** [Effect of Petroleum Coke Addition on Blends with Different Plastic Properties]. The search of possible ways for increasing the use of national raw materials and lowering coking costs led to a research program based on the domestic petroleum coke

utilization in coking blends. This report is the second of that program. Variable amounts of petroleum coke were added to blends with different plastic properties. The effect of petroleum coke addition turned out to depend upon the rheological characteristics of the base blend. The addition of petroleum coke to the blend improves abrasion strength, expressed in terms of M40 index, when the base blend has good plastic properties while it deteriorates if the base blend has poor plastic properties. The M40 index evolution shows that it improves due to less fissuring or becomes worse because of poorer bonding with reference to the base blend properties. (Author abstract) 3 refs. In Spanish.

**077294 PUFFING BEHAVIOR OF NEEDLE COKE PREPARED FROM HETEROCYCLIC COMPOUNDS.** The influence of sulfur and nitrogen on puffing was investigated separately and jointly by using needle coke specimens prepared from acenaphthylene, thianthrene (sulfur source), and phenazine (nitrogen source). Puffing is closely related to the presence of sulfur and/or nitrogen in the coke. The influence of sulfur in the coke on puffing is stronger than that of nitrogen. There is no mutual interaction of the two elements in their effect on puffing. The extent of puffing is inversely proportional to the bulk density of graphitized coke. (Author abstract) 14 refs.

Fujimoto, Ken-ichi (Nippon Steel Corp, Kawasaki, Jpn); Nagino, Hisayuki. *High Temp High Pressures* v 19 n 5 1987 p 559-565.

**Magnetic Field Effects**

**077295 EFFECTS OF A MAGNETIC FIELD ON HEAVY OIL RESIDUES AT HIGH TEMPERATURES.** The authors have measured the effects of magnetic fields on heavy oil residues at high temperatures. This was necessary because deposits (coking) may be formed in heat-transfer equipment in oil refineries. Deposition occurs in heat exchangers, reboilers, ovens, tubes, and compressors in systems for distilling petroleum, alkylation, and cracking over wide parameter ranges for liquids with boiling points up to 311°K at flow temperatures of 408-755°K with metal surfaces at 477-803°K, with the deposition most pronounced in tubular ovens in slow-coking systems. There are several ways of reducing the coking in these tube coils, which include chemical ones (the introduction of solvents) and hydrodynamic ones (increased turbulence in the flow). The authors examine the use of magnetic fields for these purposes. 11 refs.

**Manufacture**

**077296 OPTIMIZATION OF CARBONIZATION CONDITIONS FOR NEEDLE COKE PRODUCTION FROM A LOW-SULPHUR PETROLEUM VACUUM RESIDUE.** The optimum carbonization conditions for converting a low-sulphur petroleum vacuum residue in a tube bomb in terms of pressure and temperature into better needle coke of low coefficient of thermal expansion (CTE) with less production of poor bottom coke, were studied by observation of the resultant cokes and sequential analyses of carbonization intermediates by means of solvent fractionation and gas evolution. Carbonization at 460°C under 15 kg cm<sup>-2</sup> G produced the best needle coke. The quality of the resultant needle coke was strongly influenced by viscosity changes of the system, the solidifi-

cation range and gas evolution. The formation of a bottom coke of fine mosaic texture is discussed from the viewpoint of the co-carbonization concept. (Edited author abstract) 13 refs.

Mochida, Isao (Kyushu Univ, Fukuoka, Jpn); Oyama, Takashi; Fei, You Qing; Furuno, Tetsuya; Korai, Yozo. *J Mater Sci* v 23 n 1 Jan 1988 p 298-304.

## Oxidation

**077297 OXIDATION STUDIES OF VARIOUS PETROLEUM COKES.** In situ scanning transmission electron microscopy has been used to evaluate various coke samples ranging from very isotropic to ultrapremium needle-like in terms of their oxidation characteristics. Three major modes of attack were identified: a) low temperature (375°C) shallow pitting, which predominated in isotropic materials, b) high temperature (525°C) deep pitting, which appeared to be associated with highly anisotropic structures and c) edge recession, which occurred with all cokes but was most apparent with anisotropic structures. A rationale is presented which accounts for the behavior of isotropic and anisotropic cokes in oxygen. (Author abstract) 24 refs.

Rodriguez, N.M. (Auburn Univ, Auburn, AL, USA); Marsh, H.; Heintz, E.A.; Sherwood, R.D.; Baker, R.T.K. *Carbon* v 25 n 5 1987 p 629-635.

**077298 METHOD OF INVESTIGATING THE INTERACTION OF COKES WITH OXYGEN.** In the present work the authors have shown the possibility of using a differential flow-through reactor for studying the non-steady-state reaction of petroleum coke with atmospheric oxygen (volume concentration of oxygen 21%). The reactor consists of a tube with an internal diameter of 8 mm the bottom of which is filled with crushed quartz. The temperature in the reaction zone is measured by a thermocouple of the TPP type and a portable potentiometer of the PP-63 type. 7 refs.

## Production

**077299 MECHANISTIC MODEL FOR FORMATION OF COKE IN PYROLYSIS UNITS PRODUCING ETHYLENE.** Coke is formed by three mechanisms during pyrolysis processes used to produce ethylene. The mechanisms result in metal-catalyzed coke, noncatalytic coke formed from tars, and pyrocarbon coke that is produced when small precursors react with free radicals on the coke surface. The relative importance of each of the above mechanisms depends on the operating conditions, hydrocarbon feedstock, and type of reactor used. (Author abstract) 19 refs.

## Spectroscopic Analysis

**077300 SPECTROGRAPHIC DETERMINATION OF NITROGEN CONTENT IN PETROLEUM COKE.** A procedure is described for the determination of nitrogen in raw and calcined petroleum coke according to the band of cyanogen that is formed by reaction of carbon with nitrogen in the zone of an arc. The spectra were recorded on an ISP-51 spectrograph with a three-lens system of slit illumination. Experiments showed that with an argon flow rate of 5 liters/min, the difference in densities of the cyanogen band and the background is minimal, and remains unchanged when the purge rate is further increased. The residual content of nitrogen in the chamber is monitored by means of a blank experiment. The results obtained by the proposed method on raw cokes are compared with results obtained by the Kjeldahl method; for the calcined coke, they are compared with results obtained by the method of additions. The content of nitrogen in needle cokes is at the 0.2% level. The lower level for determination of nitrogen content in coke is

0.05%, and the relative standard deviation is 0.1. 6 refs.

## Testing

**077301 ABRADABILITY OF PETROLEUM PYROLYSIS COKES.** Grade KNPS pyrolysis coke as a filler in carbonaceous materials of construction (CMCs) determines their properties to a considerable degree. The coke accounts for 70-90% of the total material weight. The authors have carried out a statistical analysis of experimental data collected over an extended period (approx. 20 years); this analysis has shown that abrasability coefficient  $K_a$  essentially does not correlate with any of the basic standard quality indexes. The coefficient of correlation for the comparison pairs  $K_a/d_a$  (where  $d_a$  is the actual density) and  $K_a/V$  were found to be 0.31 and 0.07, respectively, with a significance of this value greater than 0.5. The limits of variation of abrasability for different grades of pyrolysis coke were determined. 4 refs.

**077302 CRUDE OILS AND THEIR DISTILLATES: CHARACTERIZATION BY DIFFERENTIAL SCANNING CALORIMETRY.** Differential scanning calorimetry has been used to characterize crude petroleum. A thermal fingerprint can be obtained in a short time with a single experiment. Several parameters such as the glass transition temperature  $T_g$  of the hydrocarbon matrix, temperature of crystallization, and paraffin content can be measured with good reproducibility. For the same crude, a correlation has been found between  $T_g$  and  $T_c$  for distillates prepared under the ASTM method D2892. (Edited author abstract) 12 refs.

**077303 CORRELATING THE PVT PROPERTIES OF NIGERIAN CRUDES.** Existing correlations for predicting solution gas oil ratio,  $R_s$ , and oil formation volume factor,  $B_o$ , gave standard deviations as high as 50 and 12 percent, respectively, for Nigerian crudes. New correlations developed using 503 pressure-volume-temperature (PVT) data points from 100 Nigerian crude oil reservoirs of the Niger Delta Basin are presented. The correlations for  $R_s$  and  $B_o$  predict values from different reservoirs within 6 and 2 percent standard deviations, respectively, and apply to crudes of specific gravity range 0.811 to 0.966. These correlations are applicable to other crudes with characteristics similar to those of Nigerian crudes. (Author abstract) 7 refs.

**077304 VACUUM RESIDS FROM SYRIAN AND CUBAN CRUDES AS COKER FEEDS.** Vacuum resid from Syrian crude and commercial mixed Cuban crudes were subjected to delayed coking in a laboratory batch unit under conditions simulating the commercial unit operation. It can be seen from the data that the vacuum resid from Syrian and Cuban crudes offer promise for use as coker feedstocks. The coke obtained from the Syrian and Cuban vacuum resid is distinguished by a high sulfur content, 1.5-2 times than in the coke from the high-sulfur Oxino vacuum resid. Studies have demonstrated the economic advisability of using vacuum resid from Cuban and Syrian crudes in the delayed coking process. 5 refs.

*Oils* v 23 n 5-6 May-Jun 1987 p 260-261.

**077305 METHOD FOR EVALUATING KINETIC STABILITY OF PETROLEUM DISPERSE SYSTEMS.** The authors study the phase equilibrium of PDS (Petroleum Disperse Systems) and their stability against aggregation of the asphaltene. We are proposing that the ratio of paraffinic/naphthenic and aromatic hydrocarbons in the system should be varied by introducing a model dispersion medium, and the dynamics of change of PDS composition should be noted on a triangular diagram. Data for the construction of the PDS phase equilibrium curve are given. Phase equilibrium curves, which are represented for convenience on Cartesian coordinates, offer a means for a quantitative evaluation of the kinetic stability of a PDS according to the threshold concentration of the disperse phase with a constant fraction of precipitant in the system. This procedure can be used in determining the quantity of precipitant required to achieve the necessary depth of deasphalting, or to determine the depth of deasphalting with a given consumption of precipitant.

**077306 NEW TECHNOLOGY SEEKS TO END PIPELINES' HEAVY CRUDE DILUENT.** Sponsors are nearing commercialization of a new technology for infield partial upgrading of heavy crude and bitumen which they say could eliminate the need for diluent blending of Canadian heavy oil. Production growth of Canadian heavy oil and bitumen may be slowed in the 1990's for lack of condensate to dilute the low gravity, viscous hydrocarbons for pipeline shipment. Resource Technology Associates (RTA), Boulder, Colo., reported successful results from a 30 day run of its Geotreater process 50 b/d pilot plant at Hazen Research Inc., Golden, Colo. Further, an engineering study Santa Fe Braun Inc. conducted for RTA on 10,000-50,000 b/d Geotreater units showed commercial potential, especially in Canada.

**077307 GROUP COMPOSITION OF THE LOW MOLECULAR WEIGHT NITROGEN BASES OF SAMOTLOR CRUDE OIL.** Low molecular weight nitrogen bases of Samotlor oil, extracted by aqueous and 50 percent acetic acid solutions of 25 percent sulfuric acid, are mainly quinoline derivatives containing benzene and naphthalene rings, respectively, and also thiazole derivatives. Of the non-extracted part of the ultimate concentrate of the nitrogen bases, mixed heteroatomic structures predominate, most probably in the form of thio-phenoxinolines, amides, and carboxylic derivatives of pyridine containing benzene and naphthalene rings. Fractionation of the concentrate of the nitrogen bases by the given sulfuric acid solutions occurs in accordance with increase in the molecular weight and reduction in the aromatic nature of the molecules on account of an increase in cycloalkane and aliphatic framing of the latter. 5 refs.

## Additives

**077308 INFLUENCE OF ADDITIVES OF DISPERSE COMPOSITION OF PETROLEUM.** The present work has been aimed at determining the effects on the disperse composition of crude oils from various fields (Kalamkas, Karazhanbas, Uzen', Zhetysai, Oimasha) by the addition of technical carbon (PM-100, PM-75, PM-50), light pyrolysis tar, and crude oils from other fields. The crudes from the Kalamkas and Karazhanbas fields are classed as high-resin and low-wax; the Uzen' and Zhetysai crudes are classed as high-wax; and the Oimasha crude is classed as medium-wax without any resins or asphaltene. Characteristics of the crudes are given. Disperse systems are studied by means of such physical methods as small-angle X-ray scattering, conductivity measurement, laser correlation spectroscopy, etc. 8 refs.

**Analysis** See Also ACIDS—Composition Effects; PETROLEUM GEOLOGY.

**077309 RELATIONSHIPS IN COMPONENT-FRACTIONAL AND CHEMICAL COMPOSITION OF CRUDE OILS.** The proposed series of articles, of which this is the first, reflects the results obtained by applying systems analysis methods to a large volume of analytical data for crude oils from various regions of the world. So far as, crude oils have not been previously examined in this particular aspect; therefore, the developments set forth in these articles may prove to be useful not only because of the methods and techniques that are set forth, but also in terms of the use of the very principles of mathematical systems research. Some of the relationships that a described have been found to give an adequate representation of results obtained in investigation of the composition of not only crude oils, but also products of many chemical conversions in hydrocarbon systems, particularly in natural gases and gas condensates. 8 refs.

Eigenson, A.S. (Bashkirian Scientific-Research & Design Inst of the Petroleum Industry, USSR); Sheikh-Ali, D.M. *Chem Technol Fuels Oils* v 23 n 3-4 Mar-Apr 1987 p 197-204.

**077310 ASPHALTENES IN SAUDI ARABIAN HEAVY CRUDE OIL SOLUBILITY AND MOLECULAR WEIGHTS IN HYDROCARBON SOLVENTS.** The asphaltenes from Saudi Arabian Heavy crude oil residue (370°C+) were precipitated by adding n-alkane solvents (n-C<sub>5</sub> to n-C<sub>10</sub>) to the crude oil/residue. The asphaltenes thus prepared were examined for their percent yields, VPO molecular weights and ultimate composition. VPO molecular weights were measured in five different solvents of varying dielectric constant (2.2 to 12.3). The yield and atomic H/C ratio of Arabian Heavy asphaltenes were found to decrease with an increase in the carbon number of precipitating solvent. (Edited author abstract)

Ali, Mohammad Farhat (King Fahd Univ of Petroleum & Minerals, Dhahran, Saudi Arabia); Saleem, Mohammad. *Fuel Sci Technol Int* v 6 n 5 Oct 1988 p 541-556.

**077311 CRUDE OIL FROM THE ZABURUN'E FIELD.** The oil from the Zaburun'e field is heavy (density 894.5 kg/m<sup>3</sup> at 20°C), viscous (46.3 mm<sup>2</sup>/sec at 50°C) medium-resin (content of silica gel resins 8.8% by weight), and low-pour (solid point -37°C), with small contents of asphaltenes (0.3% by weight), wax (0.02% by weight), and sulfur (0.4% by weight). Investigation of the hydrocarbon group composition of 50°C fractions of the oil showed that the fractions distilling below 350°C consist mainly of high-energy isoparaffinic and naphthenic hydrocarbons, the total content of which amounts to 82-94% by weight. The contents of naphtha fractions in the crude are very low: 1.6% by weight below 180°C, 2.5% by weight below 200°C. Lube stocks obtained from the Zaburun'e crude have high viscosity indexes, low solid points, and low sulfur contents.

**077312 SPILLS FROM LARGE CRUDE-OIL-CARRYING TRANSMISSION PIPELINES - AN ANALYSIS BY CAUSE, FREQUENCY, AND CONSEQUENCE.** The author presents for one particular type of pipeline a probabilistic assessment of the likelihood of unwanted failures, and the likely spill volumes associated with each of the main failure causes. The failure frequencies shown in this analysis are low when compared with other forms of transportation, with the mean volume of oil spilt in these failure incidents being some 100m<sup>3</sup>. Clearly, the environmental, humanitarian, and economic risks presented by any pipeline system will depend on particular circumstances, for example the pipeline routing, and

must of course be compared against those risks associated with any alternative. The analysis presented provides the type of information which can assist this comparison. Further, the author believes that the analysis also highlights those areas where maximum benefit could be achieved if it was thought necessary to expend resources on any further risk-reduction measures. 7 Refs.

**Biodegradation** See Also PETROLEUM ANALYSIS.

**077313 EFFECT OF BIODEGRADATION ON CRUDE OIL BULK AND MOLECULAR COMPOSITION.** A laboratory simulation of an oil spill was used to monitor the effect of microbial alteration on crude oil molecular, bulk and carbon isotopic compositions. The rate of microbial alteration of alkanes decreased with increasing carbon number. Straight-chain alkanes were more rapidly removed than branched (isoprenoids) hydrocarbons though ultimately even the isoprenoids were degraded. Aromatic compounds were also altered. Isomer specific degradation was observed within a given aromatic alkylation (i.e., methylphenanthrenes). The most stable properties, under the given conditions, were carbon isotopic composition, Ni/V ratios, total scanning fluorescence spectra, and various molecular distributions. **077315 PROCESO EN LECHO FIJO PARA LA DESMETALIZACION Y LA HIDROCONVERSION DE CRUDOS PESADOS Y RESIDUALES MEDIANTE CATALIZADOR DE ARCILLA NATURAL.** [Process for the Demetalization and Hydroconversion of Heavy Crudes and Residues Using a Natural Clay Catalyst]. Venezuelan heavy crudes are characterized by their high metal content. Great research effort is being devoted to upgrade this kind of feedstock in order to obtain more valuable products such as gasoline and distillates. Catalytic hydroprocessing has been considered by several oil companies as the first step to reduce the impurities to a certain level, so that the products can be efficiently processed in any downstream unit. This paper deals with the results obtained at bench scale, in the hydroprocessing of a typical Venezuelan heavy crude and its residue, using a natural clay catalyst (INT-AR3). Data on the catalytic activity for hydrocracking, hydrometalization and asphaltenes conversion is presented. (Edited author abstract) In Spanish. 4 refs.

**077321 APPLICATION OF ROBOTICS TO SIMULATED DISTILLATION ANALYSIS OF CRUDE OIL AND LUBE OIL SAMPLES.** Timely simulated distillation (SIMDIS) analysis of refinery process streams is allowing better process variable control in the petroleum industry. To satisfy the constantly increasing demand for SIMDIS analyses of crude oil (CRUDE) and lube-range (LUBE) samples, a robotics system is employed. The method used for SIMDIS analyses of such heavy samples containing residual material boiling above 1000°F requires that an internal standard material be weighed into each sample. This is a very time-intensive activity. Further, the accuracy of the manual analyses is not acceptable for process control. The use of the robotics system improves the accuracy to an acceptable level and significantly decreases sample preparation time. (Author abstract) 4 refs.

**077322 ANALYSIS OF RESIDUM DESULFURIZATION BY SIZE EXCLUSION CHROMATOGRAPHY WITH ELEMENT SPECIFIC DETECTION, PART II.** Heavy crude residua are analyzed by size exclusion chromatography with element specific detection (SEC-ICP), to elucidate structural information about the S-containing compounds. These compounds appear to fall into two categories: those which are (1) moderately small components (probably thiophenic), and (2) larger components associated with apparent precursors of asphaltene. The effects of thermal hydroprocessing on the S-containing compounds were also examined. The results indicate the S-containing compounds behave similarly to the metal-containing compounds under the same processing conditions. Possible binding site relationships between some of the S- and metal-containing compounds in heavy crudes and residua are discussed. (Edited author abstract) 65 refs.

## Composition Effects

**077327 WETTABILITY AND ADSORPTION CHARACTERISTICS OF CRUDE-OIL ASPHALTENE AND POLAR FRACTIONS.** This study relates the chemical composition of the polar compounds of crude oil to the wettability of rock/oil/brine systems. Adsorption properties of polar and asphaltene fractions were evaluated to determine their effects on wettability. Polar compound fractions were found to cause an oil-wet state on Berea sandstone, but the effects were not a function of the polar-fraction concentration. The concentration of nitrogen/sulfur compounds in six crude-oil polar fractions correlated with the wettability of the polar fractions on Berea sandstone. Langmuir-type adsorption on Berea sandstone was observed in adsorption studies of the asphaltene and polar fractions. Additional analysis with brine-saturated Berea sandstone resulted in adsorption values up to three times less than that for dry Berea. The amount of polar fraction adsorbed on brine-saturated Berea sandstone correlated with crude-oil wettability. (Author abstract) 18 refs.

Crocker, M.E. (Nat'l Inst for Petroleum & Energy Research); Marchin, L.M. *JPT J Pet Technol* v 40 n 4 Apr 1988 SPE 14885, p 470-474.

**077328 RELATIONSHIPS IN COMPONENT-FRACTIONAL AND CHEMICAL COMPOSITION OF CRUDE OILS.** On the basis of the available data, the authors propose that (beginning with the heaviest residue and down to C<sub>4</sub>, i.e., to approximately 0°C) the yield up to each particular temperature should be calculated using the equation derived by the authors. In order to eliminate these difficulties in the analysis of new crude oils, it is necessary to require that the scheme of analysis include a determination of the average MW of the crude oil by methods that eliminate the possibility of significant errors; also, in order to monitor the accuracy of analyses, this scheme must include a determination of the MW of the distillates and the residue. In the case of crude oils that have been investigated previously, but without including the indicated determinations certain calculations must be made. These calculations are presented. 12 refs.

**077329 CRUDE OIL WINDFALL PROFIT TAX ACT OF 1980: AN ECONOMIC ANALYSIS OF ITS EFFECT ON DOMESTIC CRUDE OIL PRODUCTION.** A framework is developed to examine the effects of the Crude Oil Windfall Profit Tax Act of 1980 on domestic production of crude oil that specifically takes into account both the pre-existing systems of price controls the Act replaced and the temporary nature of the tax. The Act established three categories of oil, called tiers, which are taxed at different rates on the difference between the removal price and an adjusted base price. Assuming that the market for oil is competitive, and given reasonable assumptions about extraction costs, the Act will increase the production of crude oil from tier one above the level that would have been produced had the price controls remained in effect for the same length of time, although less than the socially optimal amount of oil will be extracted from tier one while the tax is in effect. (Edited author abstract) 23 refs.

## Dehydration

**077330 POSSIBILITY OF USING ELECTRON-ION TECHNOLOGY FOR DEWATERING AND SALT-OUT CRUDE OILS.** Electron-ion (EI) technology offers promise as a means of thoroughly ridding crude oils of water and salts. EI dehydrators operate by charging the water globules by ionization in a steeply nonuniform electrostatic field and precipitation on the grounded surface of a precipitation electrode under the action of mirror-image forces. These dehydrators have been found effective in the dewatering and salt-out of very viscous heavy crudes. (Edited author abstract) 8 refs.

## Density

**077332 DETERMINATION OF DENSITY AND ITS ERRORS.** At first sight, the determination of the density of crude oil or products appears to be a simple matter. When one carries out a close scrutiny of the procedures involved one comes to the realization that, at least for crude oils, and especially for North Sea crudes which are normally shipped with a high RVP (8 psi), there is much more to the process, and in this paper the authors give a few of their ideas on the probable errors involved at the moment, and how these might be reduced in future. 1 ref.

Fitzgerald, H. (Moore, Barrett & Redwood Ltd); Fitzgerald, D. *Q J Tech Pap Inst Pet* Oct-Dec 1987 p 55-58.

## Density Measurement

**077333 DETERMINATION OF DENSITY AND ITS ERRORS.** When one carries out a scrutiny of the procedures involved one comes to the realization that, at least for crude oils, and especially for North Sea crudes which are normally shipped with a high RVP (8 psi), there is more to the process than initially meets the eye. As an indication of some of the confusion that surrounds the determination and subsequent use of a crude oil density,

there are at least eight different terms for defining the particular figure under discussion. This paper provides some thoughts on clarifying the issues. 1 ref.

**077335 DESTILACION SIMULADA DE CRUDOS: ESTUDIO DE PRECISION Y COMPARACION CON CURVAS DE DESTILACION TBP.** [Simulated Distillation of Crudes: a Precision Study and a Comparison with TBP Distillation Curves]. The proposed method of simulated distillation for crudes (ASTM D-2 Proposal P167) does not have yet the support of a precision study. This method has been used at INTEVEP for routine analyses of medium and heavy crude oils, and hydroconversion products. Data with a precision of  $\pm 3\%$ , similar to simulated distillation method for petroleum fractions (ASTM D 2887), have been obtained from repetitive analysis of some selected samples. From the comparison of distillation curves obtained by the simulated distillation method for crudes and by the ASTM D 2892 distillation method (TBP 15/5), it is observed that in crudes ranging 29 - 12°API, these curves are closer to TBP 15/5 curves in weight T than in volume %, but this difference is never larger than 3%. (Author abstract) In Spanish. 8 refs.

**077336 SURFACE PROPERTIES OF DISTILLATION RESIDUES FROM HEAVY OILS - INFLUENCE OF VISCOREDUCTION.** Liquid contact angle measurements were performed on films of heavy oil distillation residues deposited on mica plates. The results are used to calculate the dispersive component of the surface energy and also the polar interaction energy with various liquids. The residues have different surface properties, which should be taken into account during their use and processing. It is also shown that viscoreduction changes the surface energy characteristics according to the composition of the residue before such treatment. (Author abstract) 4 refs.

**077337 DIE FAELLUNG VON ASPHALTENEN AUS ERDOEL-DESTILLATIONSRUUCKSTAENDEN MIT KOHLENDIOXID.** [Deasphalting of Crude Oil Distillation Residues With Carbon Dioxide]. The use of carbon dioxide as deasphalting agent is investigated. From the experimental results the following conclusions can be drawn: The precipitation of asphaltenes with CO<sub>2</sub> is possible both at its liquid state and above its critical conditions. It is pertinent to point out that the successful precipitation of asphaltenes from crude oil distillation residues depends on favorable reaction conditions. CO<sub>2</sub>-deasphalting procedure could be grouped under the technical methods for the precipitation of asphaltenes. This work is recommended for a reaction temperature of about 40°C. **077338 COMPOSITION OF CARBOXYLIC ACIDS FROM DISTILLATES FROM TURKMENIAN CRUDES.** The authors present results obtained in a mass spectrometric study of carboxylic acids recovered from

kerosene distillates at the Krasnovodsk refinery, and the hydrocarbons obtained by decarboxylation of individual fractions of the acids. The acids were prepurified and separated by ion exchange chromatography; the aliphatic acids were segregated by urea adduct formation and were partially identified. From the results of the mass spectrometric study, it follows that the preparation of saturated hydrocarbons for investigation of the composition and structure of carboxylic acids, following scheme, is unacceptable because of losses of certain groups of acids mainly polycyclic acids, leading to an incorrect evaluation of the quantitative composition of the original acids. The data we obtained on the composition of the acids are consistent with data reported by other investigators on the composition of natural carboxylic acids. 8 refs.

**077340 FORECASTING OIL PRICES TO 1995.** Two oil price scenarios are presented - \$12/bbl and \$20/bbl - which represent attainable price trends in today's world. The data are presented in such a way that alternate prices can be analyzed as well. (Author abstract)

Jones, S.T. (Wharton Econometrics Inc, Bala Cynwyd, PA, USA). *Hydrocarbon Process* v 66 n 8 Aug 1987 p 78.A-78.B.

**077341 NEXT OIL CRISIS.** The causes and types of oil crises are identified and explained. Technical and political crises are differentiated. Changes in the world oil market since 1973 are analyzed. The ways to deal with crises are considered and the benefits of a moderate oil import tariff are pointed out. Other useful measures that can be taken to prevent or mitigate an oil crises are discussed.

Lynch, Michael. *Technol Rev* v 90 n 8 Nov-Dec 1987 p 39-45, 66.

**077342 TOMORROW'S OIL PRICES AND DEMAND.** GRI prepares an annual baseline projection of U.S. energy supply and demand as the basis for the strategic planning of its research and development program. One input to the baseline projection is an assumption of the future price track for U.S. refiners' acquisition cost of crude oil. From this price track, regional prices for petroleum products are estimated for each product and demand sector. For the analysis of future oil and gas supplies, a consistent projection of the wellhead crude oil prices that would be expected by producers is also developed. A major portion of U.S. petroleum supply is imported and as crude oil is internationally traded, the price is set in the global market. Any projection of the oil price outlook, therefore, must be based upon an evaluation of the global petroleum market outlook.

**077346 EFECTOS DE MATRIX EN LA DETERMINACION DIRECTA DE VANADIO Y NIQUEL EN CRUDOS Y DERIVADOS POR ABSORCION ATOMICA CON ATOMIZACION ELECTROTROMICA.** [Matrix Effects in the Direct Determination of Vanadium and Nickel in Crudes and Derivatives by Flameless Atomic Absorption Spectroscopy]. The dependence of vanadium and nickel absorbance signals with the nature of the matrix of different crude oils, gas oils, and some commonly used standards, as well as the dependence of the signal on ashing and atomization temperatures as obtained by flameless atomic absorption spectroscopy is studied. Different calibration curves are obtained from standard reference solutions of different organometallic compounds under identical conditions of concentration and optimum graphite tube operating parameters. The results indicate that every crude sample and standard behaves in a very particular manner, depending on its organic matrix and on the selected conditions of ashing and atomization temperatures. **Iodine Determination** See Also IODINE—Extraction.

**077347 DETERMINATION OF <sup>129</sup>I IN HEAVY RESIDUES OF TWO CRUDE OILS.** <sup>129</sup>I/<sup>127</sup>I ratios were determined in heavy residues of two crude oils which were produced from 10 Ma and 300 Ma old formations.

The measured  $^{129}\text{I}/^{127}\text{I}$  ratios were between 5 and  $10 \times 10^{-12}$ . These values are significantly above the ratios determined for marine sediments and, for the older oil, also above those supported by in situ production of  $^{129}\text{I}$  from uranium. We attribute the high level of  $^{129}\text{I}$  in the residues to addition of anthropogenic iodine during the production of the oils. The ratios indicate also that more than 90% of the iodine measured came originally from the oils. (Author abstract) 20 refs.

## Moisture

**077349 BASES FUNDAMENTALES DEL PAPEL DE LA QUIMICA DESHIDRATANTE: INFLUENCIA DE LA FORMULACION FISICOQUIMICA SOBRE LA ESTABILIDAD DE UNA EMULSION.** [Fundamentals of Emulsion-Breaking Agents Action: Influence of Physicochemical Formulation on Emulsion Stability]. The stability of a crude oil emulsion is mainly due to the presence of adsorbed natural surfactants, at crude-water interphase. The mixture of emulsion-breaking agents with natural surfactants results in very unstable emulsions. Using model systems, the influence of the physico-chemical variables on emulsion stability is determined, and conditions are found which result in unstable emulsions. The causes for the instability are discussed, and the dehydration process, is interpreted by means of a formulation-water/oil ratio map. (Author abstract) In Spanish. 80 refs.

## Moisture Determination

**077350 COMPUTATIONAL METHOD TO ASSESS CONCENTRATION OF WATER IN CRUDE OIL DOWNSTREAM OF A MIXING SECTION.** This paper describes a method for predicting the concentration distribution of water in crude oil in a pipe section downstream of a region of mixing and droplet break-up. The complexity of the problem and the necessary simplifications are described. The method with its approximations is justified on grounds of possible savings in financial outlay. Details of governing equations, computational method and boundary conditions lead on to the link between forces on the droplet and the velocity of the droplet relative to the bulk liquid. The model incorporates turbulence enhancement and decay, and secondary velocities likely to approximate to those following a T-piece or bend or swirl-creating element. The computer program was tested against data provided by BP and the results suggest that if the predictions indicate adequate mixing then they are likely to underestimate the uniformity of the mixture. (Edited author abstract) 16 refs.

## Molecular Weight

**077351 COMPOSICION Y CARACTERISTICAS FISICOQUIMICAS DE SURFACTANTES NATURALES EXTRAIDOS DE CRUDOS EXTRAPESADOS.** [Composition and Physicochemical Characteristics of Natural Surfactants From Extra Heavy Crude Oils]. Natural surfactants from Cerro Negro and Zuata crude oils were isolated; it was found that intermolecular associations that could affect the molecular weight value were absent. On the other hand, the variation in interfacial tension (oil-water) as a function of pH for crude oils, was not similar to that showed by their fractions; this indicates that such behavior results from the joint activity of asphaltenes and resins. (Edited author abstract) 9 refs. In Spanish.

## Photochemical Reactions

**077352 DESTRUCTIVE-CONDENSATION TRANSFORMATIONS OF RESINOUS CRUDE OIL BY THE ACTION OF LIGHT.** The effect of radiation from a mercury-quartz lamp PRK-2 upon native resin-asphaltene substances of Norian, Samgore and Supsin crude oils was examined. Irradiated resin substances from crude oil undergo marked changes-photochemical breakdown to form gaseous hydrocarbons (methane, ethane and propane) and photochemical condensation. During the condensation step molar mass increases and three-dimensional structures are formed, these have a high softening point (above 400°C) and do not dissolve in organic solvents. 2 refs.

## Physical Properties

**077353 CORRELATIONS OF VISCOSITY, GAS SOLUBILITY, AND DENSITY FOR SASKATCHEWAN HEAVY OILS.** The complex chemical nature of crude oil has made it extremely difficult to develop reliable models capable of predicting physical properties. Yet the importance of crude oil as a source of energy or as a precursor in chemical synthesis makes it necessary that simple equations be available that engineers can use to accurately predict these properties. Three noncomponent equations are presented which were found to accurately model the viscosity, density, and gas solubility of a wide range of Saskatchewan heavy oils. These equations were developed from previous work with extended terms to allow for additional independent parameters. The extended equations allow for variations in temperature, pressure, dissolved methane concentration, and dissolved carbon dioxide concentration. (Author abstract) 8 refs.

Quail, Beverly (Univ of Saskatchewan, Saskatoon, Sask, Can); Hill, G.A.; Jha, Kamal N. *Ind Eng Chem Res* v 27 n 3 Mar 1988 p 519-523.

**077354 HIGH-WAX CRUDE FROM ARKHANGEL OBLAST.** The Kharyaginsk crude is low-sulfur and low-resin; it is distinguished by an extremely high content of wax (21%) and a high yield of fraction below 350°C (50.1% by weight). The naphtha distillates are characterized by low octane number (40 ON for IPB-180°C cut), as paraffinic hydrocarbons predominate in these distillates. The diesel fuel cuts are characterized by high cetane numbers, very low sulfur contents, and large quantities of straight-chain paraffinic hydrocarbons. The dewaxed 200-320° and 200-350° cuts (respective yield 9.1% and 14% one crude) have respectively solid points below -61° and below 50°C; they can be used as components of winter-grade diesel fuel. The lube cuts contain about 40% solid

waxes. 3 refs.

Processing See Also HEAT EXCHANGERS—Costs; HYDROCARBONS—Coking.

**077355 PHARMACEUTICAL WHITE OIL FROM WEST SIBERIAN CRUDES.** A pharmaceutical white oil meeting the requirements of GOST 3164-78 has been obtained from West Siberian crudes. This oil is very similar in physicochemical properties and also in content of aromatic hydrocarbons to the commercially manufactured pharmaceutical white oil. A comparison of the structural-group composition of these oils indicates that they differ in elemental composition, content of carbon in naphthenic rings ( $C_n$ ) and paraffinic chains ( $C_p$ ), and number of rings in the average molecule. This means that these oils have been obtained from raw materials that differ in chemical nature. 6 refs.

Potatina, V.A. (All-Union Scientific Research Inst for Petroleum Processing, USSR); Drenova, T.I.; Ponomareva, T.P. *Chem Technol Fuels Oils* v 23 n 1-2 Jan-Feb 1987 p 65-67.

**077356 LA EMULSION DE BITUMEN ORINOCO EN AGUA (ORIMULSION) COMO COMBUSTIBLE EXCEPCIONAL EN PLANTAS TERMOELECTRICAS.** [Orinoco Bitumen-in-Water (Orimulsion): Un-tapping an Unlimited Premium Fuel]. Venezuela has extensive recoverable reserves of extra heavy crudes and natural bitumens located in the Orinoco Oil Belt. INTEVEP, S.A. and LAGOVEN, S.A. have developed the Orinoco bitumen-in-water emulsion (ORIMULSION) for the production, handling and transportation of those hydrocarbons. This emulsion is considered a premium fuel due to its performance in conventional liquid firing systems. Pilot scale combustion tests have demonstrated the technical feasibility of burning this natural fuel with high combustion efficiency values (99.90%). This allows to forecast a promising future for ORIMULSION as a new fuel for thermal power stations. (Edited author abstract) In Spanish. 1 ref.

**077357 DESALTERS CAN REMOVE MORE THAN SALTS AND SEDIMENT.** A properly designed and operated crude oil desalter is capable of removing much more than chloride salts and sediment from crude oil. Crude and residual fuel desalting can be used to remove water-soluble contaminants such as salts, acids, and bases; water-insoluble contaminants such as salts, basic sediment, filterable solids, and some heavy metals; and it can remove brine water from the crude. 5 refs.

Barnett, Jack W. (Petrolium Corp, Houston, TX, USA). *Oil Gas J* v 86 n 15 Apr 11 1988 p 43-44, 48-49.

**077358 PRODUCTION OF LOW-FREEZING FUEL FRACTIONS FROM MIXED PARAFFINIC CRUDES.** The authors have investigated the possibility of producing fuel fractions from paraffinic crudes. The initial crystallization temperature of fuel fractions from mixed paraffinic crudes, as a function of the yield relative to original crude is presented. With a required initial crystallization temperature of -60°C, a fuel fraction is obtained with an end point of 235°C and a yield of only 13.97% by weight on crude. The authors show the depression of the initial crystallization temperature and the content of aromatic hydrocarbons in the fuel fractions distilled from the hydrogenated products obtained on the different catalysts under different process conditions, and also the yield of these fractions as a function of the process temperature. Under the experimental conditions, the yield of the desired fraction is 81% by weight, and the process

increases the content of aromatic hydrocarbons from 15.5% to 19% by weight. Based on the test results, the process of selective hydrocracking can be recommended for the production of low-freezing middle-distillate fuels from paraffinic crudes. 2 refs.

Sultanov, S.A. (Acad. of Sciences of the Azerbaijan SSR, USSR); Rustamov, M.I.; Nefedov, B.K.; Gasanova, Zh.I.; Musaeva, S.G.; Konoval'chikov, L.D.; Konoval'chikov, O.D. *Chem Technol Fuels Oils* v 23 n 7-8 Jul-Aug 1987 p 310-313.

**077359 PRODUCTION OF PITCHES IN EXHAUSTIVE CRUDE OIL PROCESSING SCHEMES.** The author examines possible variants in obtaining petroleum pitches and pitch distillates in exhaustive crude oil processing schemes. It is shown that petroleum pitches for various applications can be obtained in special process sections added to commercial units receiving or processing pyrolysis tar. The processing of pyrolysis tar includes recovery of the light part (drying oil fraction). If the feed to the pitch production section consists of the total pyrolysis tar, the pitch section includes a vaporizer to remove the light part of the tar, distilling below 200°C. Pyrolysis pitch, in comparison with cracking pitch, is obtained under milder temperature conditions, but at a higher pressure in the pitch-forming reactor. 13 refs.

Dolmatov, L.V. (Ufa Petroleum Inst, USSR). *Chem Technol Fuels Oils* v 23 n 7-8 Jul-Aug 1987 p 313-315.

**077360 FOOD FROM CRUDE OIL VAPOR.** The synthesis of protein from petroleum involves the growing of microorganisms on various petroleum substrates and harvesting dried microbial cells as a product. Many species of yeast and bacteria are applicable so that the product is sometimes referred to as single-cell protein (SCP). Depending on the organism, the protein content can range from 40 percent to 80 percent; the remainder of the material consists primarily of nucleic acids, carbohydrates, lipids, and minerals. A number of petroleum hydrocarbons can serve as a source of carbon and energy for the microbial growth; however, methane and the normal C<sub>10</sub> to C<sub>20</sub> alkanes are most likely to produce worthwhile results. The author grew 2.5 g of yeast in a flask filled with 100 mL of water and 50 mL of crude oil. She observed that yeast grew in the mixture within 24 h. She removed the yeast from oil using centrifugation and flocculation. The yeast weighed 20 g. It was found that it was possible to grow protein on hydrocarbons above the mixture, instead of in it as was previously done. This process avoids the costly and difficult step of separating the product from the petroleum substrate. In the future this method could probably be adapted for mass production purposes by having rolls of nets or cloths on reels running across a vat used to store crude oil in factories. A beneficial factor of this process is that the synthesis of yeast uses up some nitrogen from the crude oil. 4 refs.

Burrows, Christine (Duke Univ, Durham, NC, USA). *CHEMTECH* v 18 n 7 Jul 1988 p 422-423.

**077361 ISOLATION AND FRACTIONATION OF THE NITROGEN BASES FROM PETROLEUM.** A method of differentiated isolation of basic nitrogen compounds from petroleum was developed, consisting in obtaining an ultimate concentrate of bases by means of 25 percent sulfuric acid in an 80 percent acetic acid solution with its subsequent fractionation by aqueous and water-acetic acid (1:1) solutions by 25 percent sulfuric acid. It was established that the ultimate concentrate contains nitrogen bases recovered from the hydrocarbon part of the petroleum, and a negligible amount of nitrogen bases recovered from the resin part (approx. 5 percent). The possibility of extraction separation of ultimate concentrate with the obtained products containing only strongly basic nitrogen and the residue with weakly basic nitrogen concentrated in it was shown. 10 Refs.

**077362 USE OF DRAG REDUCER CHEMICAL IN**

**THE BASS STRAIT CRUDE OIL PRODUCING SYSTEM.** Esso Australia Ltd (on behalf of the Esso/BHP joint venture) operates a crude oil and natural gas processing system based on the offshore fields in Bass Strait. Crude oil is discharged from the offshore fields via a 132-km pipeline to the crude stabilization plant at Longford. A 187-km pipeline is then used to transfer stabilized crude to Long Island Point, where the oil is held in storage prior to discharge to Australian refineries and to export. Without the use of drag reducer chemical, Bass Strait crude production is limited by pipeline hydraulic capacity. Since the last quarter of 1983, drag reducer has been injected at both Halibut platform and Longford as required to meet the demand for crude oil. As a result, daily production rates have been increased by more than ten per cent. (Edited author abstract) 1 ref.

## Pyrolysis

**077363 EFECTO DE LA ATMOSFERA AUTOGENA PRODUCIDA DURANTE LA ACUATERMOLISIS DE UN CRUDO EXTRAPESADO DE LA FPO.** [Effect of Autogenous Atmosphere During the Aquathermolysis of an Extra-heavy Oil from the Orinoco Oil Belt]. The effect of hydrogen sulfide (H<sub>2</sub>S) and carbon dioxide (CO<sub>2</sub>) on the properties of an extra heavy crude oil from the Orinoco Oil Belt is evaluated. The H<sub>2</sub>S and CO<sub>2</sub> are produced by steam stimulation of Cerro Negro, Piritul and Jobo whole cores. By using additives with the steam, we are able to quantify the effect of the atmosphere generated during aquathermolysis of the Cerro Negro whole cores (autogenous atmosphere), on the viscosity of the crude oil, and on the re-distribution of the organosulfur compounds. (Author abstract) In Spanish. 7 refs.

**Rheology** See Also HYDROCARBONS—Phase Transitions.

**077365 RHEOLOGICAL PROPERTIES OF DAQING CRUDE OIL AND THEIR APPLICATION IN PIPELINE TRANSPORTATION.** The variation of the rheological properties of Daqing waxy crudes with their thermal history and their time effect are discussed. Rheological properties of Daqing crude were determined in the laboratory with rotational viscometers and U-tube devices. The feasibility of using the proper heat treatment to improve the low-temperature flow property of Daqing crude was studied. Field tests on three long-distance heated-crude pipelines showed good agreement with laboratory measurement. A mathematical model for determination of the optimum operation parameters of pipeline transportation is also given. (Author abstract) 13 refs.

Yan, Dafan (East China Petroleum Inst, China); Luo, Zheming. *SPE Prod Eng* v 2 n 4 Nov 1987 SPE 14854, p 267-276.

**077366 STUDY OF POUR POINT DEPRESSION OF PUCHENG CRUDE OIL BY MEANS OF HEAT TREATMENT AND ADDITIVES.** In order to transport the Pucheng waxy crude oil under normal conditions, a combination method of heat treatment and additive application was investigated. The additive, pour point depressant EVA was used in combination with an oil soluble surfactant. Satisfactory results were obtained. Under the most favorable conditions, the pour point of the crude oil could be lowered as much as 23-27°C and the apparent viscosity was reduced to a value below 0.2 Pa·s with a combination additive dosage of 100 to about 300 ppm. In addition, the low temperature flow property of the crude oil was remarkably improved and a great change in rheological properties of the crude oil was observed. The effects of operating conditions, such as the temperature of heat treatment, the mode of cooling, the final temperature, the concentration of additive solution, etc. were examined. In the course of investigation, a crusting phenomenon over the surface of crude oil was observed. (Edited author abstract) In Chinese. 13 refs.

## Sampling

**077367 CRUDE OIL FROM TENGIZ FIELD.** The oil is light, low-pour, and high-wax, with low percentages of resins, asphaltenes, and sulfur. With regard to metal content, the oil contains practically no vanadium or nickel. The light part of the crude contains considerable quantities of C<sub>4</sub>-C<sub>6</sub> n-alkanes, about 50% by weight on the cut, or 2.44% on crude. The naphtha cuts distilling below 200°C consist mainly (60-73% by weight) of alkanes, including 15-23% n-alkanes, and 17-27% cyclanes. The 120-230° and 120-240°C jet fuel cuts have good combustion quality and viscosity properties, low initial crystallization temperatures, and very high contents of mercaptan sulfur, several times the maximum allowed in Ts-1 and RT jet fuels. The kerosene cuts are high in acidity and sulfur content.

## Solubility

**077368 CRUDE OIL DISSOLUTION IN SALINE WATER.** The solubilities and diffusion coefficients of crude oils having API° ranging from 11 to 28 have been measured in distilled and saline water of 44 g L<sup>-1</sup> NaCl at temperatures 25, 35, and 45°C. A linear relationship was observed between the maximum oil solubilities in distilled water and those in saline water for all the crudes over the range of temperature studied. The Setschenow salting-out parameter was found to be 0.125 independent of temperature and API°. Such a parameter is valuable in estimating the crude oil solubilities in waters of different salinity. An analytical solution for unsteady-state diffusion was done using Fourier series. A linear relationship was found between the diffusion coefficient of oils in distilled water and those in saline water. Observed data for diffusion coefficients of the oils have been correlated in terms of API°, temperature and ionic strength with an average absolute deviation of 2%. (Author abstract) 10 refs.

**077369 NMR USED FOR SAUDI CRUDE ASPHALTENES.** Nuclear magnetic resonance (NMR) spectroscopy with proton (1H) and carbon 13 (13C) has been used to determine the structural characteristics of

asphaltenes from four commercial Saudi Arabian crude oils. These characteristics are important to refiners that have deep conversion processes to determine yields from the residual fractions of the Saudi crudes, and to determine the operating parameters of the process units. The spectra obtained give some structural similarities among the crude oils, as well as some differences. Values of various structural parameters have been tabulated from the spectra. 3 refs.

**077370 DECONVOLUTION TECHNIQUE FOR DETERMINING THE INTRINSIC FLUORESCENCE DECAY LIFETIMES OF CRUDE OILS.** A simple deconvolution procedure using FT was developed for determining the average lifetime of samples excited by a nitrogen laser pumped dye laser operating at 428 nm. To overcome the noise limitations imposed by including higher frequency harmonics in the analysis, we used an alternative approach. This approach relied on taking the Fourier transform at 21 subharmonic frequencies and using an appropriate weighting procedure in the calculation of amplitude and lifetime of the sample impulse response. A single exponential decay was assumed. (Author abstract) 9 refs.

**077371 CARATTERIZZAZIONE DEL GREZZO ITALIANO VEGA.** [Characterization of the Italian Vega Crude Oil]. The Vega crude oil (Ragusa, Italy), extracted from the largest Italian offshore oil field about 25 km off the coast of southern Sicily, could represent a significant resource for the national economy. A multidisciplinary approach is presented for elucidating the physicochemical properties of the Vega crude oil at a molecular level. The physicochemical parameters indicate that the Vega oil is a heavy product with a low content of light-boiling fractions. Spectroscopic data (IR, UV, NMR) indicate an average molecule with an aromatic-naphthenic structure and a high 'compactness index'. The spectroscopic results for the Vega oil have been compared with those of other crude oils. Some relationships between the spectroscopic data and the asphaltene content of various crudes have been found. (Edited author abstract) 22 refs. In Italian.

**Stability** See Also HYDROCARBONS—Recovery.

**077373 INTENSIFICATION OF CRUDE OIL STABILIZATION PROCESS.** Light crudes, after dehydrating and desalting, must be stabilized by taking off the propane-butane cut and sometimes the pentane cut. Stabilization is aimed at reducing the losses of valuable hydrocarbons in transportation and storage, and also at the delivery of crude to the refinery with a constant vapor pressure. In order to evaluate the applicability and select

a reliable analytical relationship for calculating phase equilibrium constants of individual components, the authors performed a calculational analysis in the examples of 20 samples of oil-in-place from fields in West Siberia. 6 refs.

**Storage** See Also OIL WELL PRODUCTION—Offshore.

**077374 PETROLEUM PRODUCT STORAGE BY COMPETITIVE CRUDE OIL PROCESSORS.** This paper presents and tests a model of the storage behavior of competitive crude oil processors. A formalization of the decision problem of such a firm is first presented that permits the derivation of behavioral relations for stocks of crude and refined oil products. Given explicit functional forms, it is possible to test for the existence of such relations empirically. The relations are tested using data from the United States market for distillate fuel oils. The data provides strong support for the model in its linear form. However, there is evidence that the true relationship is non-linear. (Author abstract). 17 Refs.

**Structure**

**077375 MODEL OF COMPLEX STRUCTURAL UNIT IN CONDENSED MEDIA.** In support of the proposed CSU (Complex Structural Units) model, we have analyzed experimental data relative to the heats of mixing of compounds of different classes present in crude oil (paraffins, naphthenes, aromatic hydrocarbons). The strongest interaction is observed between aromatic compounds; therefore, in the systems under consideration, aromatic compounds are the core-forming components of the CSU. With increasing length of the alkyl radical in the molecule of the aromatic compound, the heat of mixing in these systems increases. Compounds of the naphthenic series in these systems interact better with paraffins than with aromatic hydrocarbons. 5 refs.

**Thermodynamic Properties**

**077377 BIRBA FIELD PVT VARIATIONS ALONG THE HYDROCARBON COLUMN AND CONFIRMATORY FIELD TESTS.** This paper describes a practical application of thermodynamic modeling that indicated that the PVT properties of the reservoir fluid in the Birba field were strongly depth-dependent, explaining the presence of significantly undersaturated oil only 200 m [655 ft] below a gas cap. Field tests confirmed the thermodynamic model to be correct. Furthermore, this paper discusses the options for field development, including the consideration of possible benefits of (developed) miscibility when gas is

injected. (Author abstract) 4 refs.

**Trace Analysis**

**077379 TRACE-METAL DISTRIBUTION IN MOSLAVINA BASIN CRUDE OIL AND OIL PRODUCTS.** Crude oil from the Moslavina basin was found to have very low abundances of the trace metals vanadium, nickel, iron, sodium, potassium and calcium, ranging from a minimum of 0.02 to a maximum of 16 µg g<sup>-1</sup>. Of the metals originally presented in the crude oil, nickel had the highest means mass yield of 6.0 µg g<sup>-1</sup>, vanadium the lowest (0.5 µg g<sup>-1</sup>). The metal abundances determined in oil distillation products (light gas oil, heavy gas oil and atmospheric residue) were low. Vanadium and nickel were primarily identified in the resin fraction of Moslavina oil, proving them to be mainly associated with the less polar constituents of intermediate molecular mass. Investigation of trace metal distribution in products of atmospheric distillation of Moslavina oil showed that up to a temperature limit of 350°C metals evaporated only slightly; they could not be detected in the petrol fraction. In the course of the processing procedures ~90% of all the trace metals present in crude oil was concentrated in the atmospheric residue. (Edited author abstract) 25 refs.

**Transportation** See Also OIL WELL PRODUCTION—Sub-sea Production System.

**077380 LOSSES IN THE SHIPMENT OF CRUDE OIL: RECENT DEVELOPMENTS IN ANALYSIS AND QUANTIFICATION.** The underlying problem in the reconciliation of oil measurements for the purpose of loss control is the identification and quantification of real losses as opposed to apparent losses due to measurement error. An overall material balance provides a useful framework for analysis. The results of a recent pilot study of oil loss statistics, derived from conventional voyage files for liftings of Middle East crude parcels during 1984/86, are presented. The factors which govern evaporative loss are identified and discussed. The magnitude of crude evaporative losses during loaded passage is considered from fundamental principles. Predicted transit losses are relatively small and lie within the 95% confidence limits derived from the pilot study. (Edited author abstract) 14 refs.

**Vaporization**

**077381 INVESTIGATION OF THE EFFECTS OF PRESSURE AND TEMPERATURE ON THE VAPOURIZATION CHARACTERISTICS OF CRUDE OIL USING FIRST APPROXIMATION THERMAL ANALYSIS.** This study investigates the effect of pressure and temperature on crude oil vaporization using first approximation thermal analysis. Developed here is a technique for quantifying the vaporization

of fractions of a crude oil using an experimentally obtained thermogravimetric curve of the crude. The initial data utilized is the weight loss versus temperature values at atmospheric pressure, together with physical property data and equilibrium constant,  $k$  values. The results of this study allow the estimation of the volume of oil distilled underground when steam is injected into oil reservoirs at varying pressures and temperatures to recover crude oil. (Author abstract) 7 refs.

**077382 SIMULACION FLUIDODINAMICA DE UN REACTOR DE HIDROCONVERSION A ESCALA LABORATORIO.** [Fluidodynamic Simulation of a Hydroconversion Reactor at Bench Scale]. The fluid dynamics of a laboratory reactor employed for the hydrovisbreaking of Cerro Negro crude oil was simulated. A cold model reactor in plexiglas using kerosene-air and water-butanol-air fluid streams were employed to determine the effect of a number of trays and the open area on them, with or without thermowells. It was demonstrated that gas hold-up is affected by the presence of the thermowell and the trays. Liquid dispersion depends on gas flow and on the number and type of trays. Under stable flow conditions the experimental dispersion coefficients could be predicted from the Ohki-Inoue equation. (Author abstract) In Spanish. 24 refs.

**077383 VISCOSITY OF CRUDE OIL BLENDS.** The viscosities of light, medium, and heavy crude oils and the viscosities of their blends were experimentally measured over a temperature range of 10-60°C. These viscosity data were used to develop a new method for predicting the viscosity of crude oil blends based on known component viscosity. In addition, ASTM D341 and Refutas index methods were evaluated for predicting viscosities of crude oil blends. It was found that the new method gave the best representation of experimental results. The deviation in most cases was less than 6%. (Author abstract) 14 refs.

**077384 VISCOSITY CORRELATION FOR DEAD, LIVE AND UNDERSATURATED CRUDE OILS.** The predictive accuracy of the existing correlations used to estimate dead, live and undersaturated oil viscosities, was tested against 1270 data points. The relative performance of each correlation was determined using statistical methods. It was found that Beal's correlation gave accurate results for dead oil viscosity. For live oil viscosity, Chew and Connolly correlation proved to be more accurate than the others. This correlation was extended to cover a wide range of solution gas-oil ratio and new equations were developed to estimate the slope (B) and the intercept (A). For undersaturated oil viscosities, none of the available correlations yielded satisfactory results. Therefore, a new correlation was developed from plotting values of (P-Pb) versus ( $\mu$ - $\mu_p$ ) on log-log paper. The plots revealed a series of straight lines of a constant slope. Each line represented oils of a particular API gravity. The new correlation showed excellent results when tested against the measured data. (Author abstract) 3 refs.

**077385 GENERALIZED KINEMATIC VISCOSITY-TEMPERATURE CORRELATION FOR UNDEFINED PETROLEUM FRACTIONS.** A generalized kinematic viscosity-temperature correlation for undefined

liquid petroleum fractions has been developed to represent the data for a wide range of temperature from 100 to 400°F. The correlation is based on experimental kinematic viscosity data from twelve TBP fractions of Arab heavy, Arab medium and Arab Berri (extra-light) crude oils with boiling ranges between 200 and 850°F. The only characterization properties required for estimation are the API gravity and 50% boiling point. Detailed analysis shows that the proposed correlation fits the data from 102 experimental measurements of kinematic viscosity, made on 34 world crude oil fractions, with an overall absolute error of 7.4%. (Author abstract) 18 refs.

**077386 REGULATION OF DISPERSITY AND RHEOLOGICAL PROPERTIES OF HIGH-VISCOSITY CRUDES.** A study is made of the degree of dispersity and the rheological properties of crude oils from the Mangyshlak Peninsula when they are compounded. The crudes used in this study were high-wax crudes from the Uzen' and Zhetybai fields and high-aromatics crudes from the Kalamkas and Karazhanbas fields. It was found that the dependence of the viscosity of the ratio of blend components can be explained by the sharp change in size of the asphaltene associates, which in the actual system are nuclei of the disperse particles. Thus, the ratio of components in crude oil blends influences the degree of dispersity of colloidal formations in these blends. This is turn governs the viscosity of the blends. We also found that the shearing stress in the system influences the variation of viscosity of the crudes and blends. Data show conclusively that the degree of dispersity and rheological properties of high-viscosity crudes are influenced by two basic factors: the specific ratio of components in the blend ('from within') and the intensity of energy supply. 6 refs.

## PETROLEUM ENGINEERING See Also PETROLEUM INDUSTRY.

**077387 ROLE OF THE ENGINEER IN THE PETROLEUM E&P INDUSTRY IN THE YEAR 2000.** This paper examines the role of engineers in major oil companies during the period from 1986 to 2000. It looks at both the majors' involvement in petroleum E&P and the significant technical challenges facing the industry for the remainder of the 20th century. The paper forecasts the functions of the engineer during this period, the computer support available to the engineer in the year 2000, and the qualifications required of the entry-level engineer in 2000. (Author abstract) 5 refs.

Jorden, James R. (Shell Development Co). *JPT J Pet Technol* v 39 n 10 Oct 1987 SPE 15346, p 1237-1242.

**077388 PETROLEUM SERVICE COMPANY ENGINEER IN THE YEAR 2000.** This paper details the technical problems that the engineer will have to face and the qualifications that will be required of an entry-level service-company engineer in the year 2000. The environment in the year 2000 in which the E&P service-company engineer will have to function is addressed as background to these forecasts. Projections are provided for the likely economic, political, and business climates. By the year 2000, there will be far fewer international service companies, but they will be larger and more capable. The service-company engineers will have to understand better the needs and problems of the international oil companies because they will have to work in partnership with the international companies personnel in mostly hostile environments. (Edited author abstract) 13 refs.

**077389 PROFESSIONAL AND TECHNICAL ROLES CONFUSED.** There are two classes of profes-

sionals: (1) those who produce ideas, data, correlations, and procedures, and (2) those who apply the output of (1). Both are equally important, although the former tend to be accorded more prestige. The deterrents that exist in the effective technical communication between the two groups is discussed. Also examined is a growing recognition of the technician factor. More professionals, even the younger ones, are awaking to the reality that too much of their time is spent doing work that a technician can do, more cheaply and profitably. Examples demonstrate this situation. Measures for corrective action are outlined.

**077392 NEW INTERPRETATION OF RECOVERY MECHANISMS IN ENRICHED GAS DRIVES.** This paper provides a new interpretation of multiple-contact miscible oil recovery processes by enriched gas drives. Using an example of solvent design for an Alberta reservoir it is shown that the low-pressure enriched gas drive is not always a condensing process as traditionally assumed by the industry. Often the process is a vaporizing drive qualitatively different from a high-pressure lean gas drive. This interpretation of process mechanism is supported by equation of state calculations which offer further insight into factors determining the process type for a given combination of reservoir fluid, solvent, reservoir temperature and operating pressures. The relationship between the solvent pressure-temperature phase and reservoir conditions is the most important factor. The vaporizing mechanism is favoured when the reservoir temperature is high and the solvent is lean in components heavier than propane. A limited review of the literature dealing with condensing gas drives was conducted and the

recovery mechanisms of several ongoing or planned miscible projects in Alberta were examined. The analysis indicates that many of these are vaporizing gas drives. (Edited author abstract) 18 refs.

## Economics

**077394 COMPARING COST ESTIMATES OF PROCESSES AT DIFFERENT STAGES OF DEVELOPMENT.** The technical and economic feasibility of eleven oil shale beneficiation and recovery process alternatives has been investigated. Because of the wide variation of engineering and cost information available, the most accurate conventional evaluation method warranted by the data has been applied to each process. To compare on a uniform basis, all alternatives have also been evaluated using the rapid modular estimation method. The results are in good agreement and thus increase confidence in the investigation and provide a good test of the rapid modular estimation (RME) method. 16 refs.

KJumpar, Ivan V. (MIT, Cambridge, MA, USA); Weiss, Malcolm A. *Eng Costs Prod Econ* v 13 n 3 Mar 1988 p 183-188.

**077395 NET VALUES OF OUR INFORMATION.** Petroleum engineers are producers primarily of information, and they flourish according to the value of the information they produce. In a very real sense, the most important decisions petroleum engineers make are choices of which information to produce. A method to guide these decisions on the basis of net value of information produced or purchased is presented in this paper. A simple decision tree is used to quantify net information values with four petroleum engineering examples. For each example, the method guides the decision to obtain (or not to obtain) information. The maximum that can be paid for information is shown. Finally, the effect of oil price on net values of information is treated. A lower oil price can actually increase the value of information. 25 refs.

## Education

**077396 PETROLEUM ENGINEERING EDUCATION IN THE YEAR 2000.** The curricula for most undergraduate petroleum engineering programs are similar because of the accreditation criteria specified by the Accreditation Board for Engineering and Technology (ABET) and SPE. Changes in curricula occur gradually. There will probably be no major changes in petroleum engineering curricula by the year 2000. New technology is incorporated into the curricula yearly. More emphasis will probably be placed on economics, communication skills, and a better overall understanding of the petroleum industry. Also, petroleum engineering departments need to develop ways to stabilize their faculties during the large swings of the boom-and-bust cycles of the petroleum industry. (Edited author abstract)

Von Gonten, W.D. (Texas A&M Univ, TX, USA). *JPT J Pet Technol* v 39 n 10 Oct 1987 SPE 15347, p 1253-1255.

**077397 MORE DIVERSIFIED PETROLEUM ENGINEERING EDUCATION FOR NEW ENERGY CHALLENGES.** Although the most diversified petroleum engineering program possible should be provided for our undergraduates, such a program cannot be at the expense of our current core programs. An undergraduate curriculum emphasizing basic science and engineering is our best assurance that our graduates can contribute to society in spite of cyclic demand for petroleum engineers. Petroleum engineering departments and the profession should anticipate the need for engineers to develop alternative energy sources, but this is not expected to affect petroleum engineering programs significantly before the turn of the century. These changes, when they do come, most likely will and should occur first in graduate programs. (Author abstract) 1 ref.

**077399 FUTURE OF LPG AS A PETROCHEMICAL FEEDSTOCK - AN ANALYSIS FOR 1980-1990.** The LPG industry needs to recognize the special needs of the chemical industry and offer LPG prices indexed to alternative chemical feedstocks. In return the chemical industry offers the opportunity of absorbing surplus LPG supplies and thus stabilizing prices in the traditional LPG markets. This paper was originally presented at the Asian Council on Petroleum (ASOPE) Conference in Malaysia in 1985 and a modified version was also given at the 1986 LPG-ITA AGM in Scotland. Despite the chaos which has prevailed in oil product markets since the beginning of 1986, the paper still stands up to scrutiny, since it mainly discusses LPG price ratios and relationships with other products, rather than specific prices. (Edited author

## Combustion

**077401 CHARACTERISTICS OF OPEN LPG JET FLAMES IN HELICAL AND TANGENTIAL-SLOT SWIRL BURNERS.** This paper reports the characteristics of LPG diffusion flames in a swirl burner in which the swirling air flow is generated by three spiralling air jets issuing from the helical grooves. The performance of the helical swirl burner (HSB) is compared with a conventional tangential-slot swirl burner (TSB) of the same diameter and under identical amounts of fuel and air flow rates. The data obtained for the two burners on flow velocity components, static pressure and central recirculation zone in isothermal flow and flame stability and flame temperature mapping have been presented. It is observed that the HSB produces higher swirl intensity compared with the TSB at the burner exit. The geometry of the central recirculation zone analyzed in the two burners indicates that the average residence time is higher in the HSB than in the TSB. Additional study results are discussed. (Edited author abstract) 10 refs.

## Manufacture

**077402 NEW LPG PLANT WILL EARN EXPORT DOLLARS.** When the LPG plant now being commissioned at Kwinana near Perth comes on full stream, it will have the capacity to process 320TJ/d of gas originating from the Northwest Shelf project and arriving via the Dampier-Bunbury pipeline. Utilising the latest cryogenic technology, the plant will produce about 113,000t/a of propane and about 54,000t/a of butane, as well as smaller quantities of heavier gases. The plant is divided more or less equally between its liquid extraction part (LEX) and its offsite facilities. The liquid extraction portion of the plant encompasses dehydration, extraction, fractionation and treating facilities. The offsite facilities include gas storage tanks, loading equipment, and the power and control systems.

Grad, Paul. *J Inst Eng Aust* v 60 n 16 Aug 5 1988 p 44-45.

## Measurements

**077403 HOW TO CHECK METERING SYSTEMS ON AN LPG LINE.** A check list is presented that can be used to check metering and custody transfer systems. Check metering systems should be reviewed along with custody transfer systems. This is to ensure not only that they are adequate, but also that both systems are metering exactly the same stream. A discussion is presented of: pulsation variation, fouling, control system effects, inlet strainers, meters and proving considerations. Factors relating to a sampling system review are also presented. 5 Refs.

**Recovery** See HYDROGEN—Recovery.

**Storage** See Also PIPING SYSTEMS—Safety Valves.

**077404 AI-KILLED STEEL PLATES FOR LPG STORAGE TANKS.** Investigation has been made on the properties of continuously cast 38 mm thick SLA37 steel plates for LPG storage tanks. The crack arrest toughness  $K_{Ic}$  of the steel plates manufactured by Kawasaki Thermomechanical Rolling (KTR) and Multipurpose Accelerated Cooling System (MACS) processes was higher than 600 kgf/mm<sup>3/2</sup> at -50°C. In vertical MIG, TIG, SAW, and horizontal SAW of steel plates manufactured by the quenching and tempering (QT) process, and in EGW with a high weld heat input of 65 to approximately 115 kJ/cm of QT, KTR, and MACS steel plates, bond properties measured at the fusion line of welded joints are 7 kgf-m and over in JE-50°C, 0.3 mm and over in -50°C COD value, and 470 kgf/mm<sup>3/2</sup> in  $K_{Ic}$ . The foregoing results proved the technical feasibility of the production of SLA37 steel plate for LPG storage tanks by using the combination of continuous casting and QT, KTR and MACS processes. ## Venezuela

**077405 LP-GAS IN VENEZUELA.** All LPG for Venezuelan consumption and export is obtained from the processing of natural gas. Until December, 1985 only 5,000 barrels per day were available for export. During that month, a large cryogenic gas processing plant facility came on-stream. At capacity, an additional 50,000 barrels per day of LPG supplies will become available. (Edited author abstract)

**077406 OCCURRENCE AND GEOCHEMICAL SIGNIFICANCE OF LONG-CHAIN DIALKYLTHIACYCLOPENTANES.** The authors report the conclusive identification and geochemical significance of long-chain 2,5-dialkylthiacyclopentanes of type 1, occurring as major components in some heavy sulfur-rich crude oils. In addition to providing new information about the 'aromatic' fractions of these crude oils (which are in fact largely non-aromatic), these results give useful indications of some of the mechanisms of incorporation of sulfur into organic matter in the sub-surface environment. Furthermore, as confirmed by thermal simulation experiments, these dialkylthiacyclopentanes are thermally labile, which seems to restrict their occurrence to immature crude oils. They could therefore serve as useful maturation parameters for the early stages of petroleum formation in carbonate basins. (Edited author abstract) 20 refs.

**077407 STEROIDAL HYDROCARBONS OF THE KISHENEHN FORMATION, NORTHWEST MONTANA.** The Oligocene Kishenehn Formation of northwest Montana and southeast British Columbia consists of fluvial and lacustrine sediments (marlstones, lignites and oil shales) deposited in an elongate, intermontane half-graben. The petroleum source rock potential and steroidal hydrocarbon distribution of selected shales of the Kishenehn Formation were examined. Several steroidal hydrocarbon series were documented, including 4-desme-

thylsteranes, 4-methylsteranes, sterenes, diasterenes, spirosterenes, C-ring monoaromatic steroids and B-ring monoaromatic anthrasteroids. Non-steroid hydrocarbons present include hopenes,  $\beta\beta$ -hopanes, moretanes, perylene, botryocane, a series of alkylcyclohexanes, and a fused-ring aromatic tentatively identified as a tetrahydrochrysene. Source rock analysis indicates that the Kishenehn Formation possesses excellent petroleum source potential. Conventional thermal maturity parameters (vitrinite reflectance and Rock-Eval  $T_{max}$  values), as well as maturity parameters derived from molecular parameters (n-alkane, steroid and hopanoid distributions) suggest that much of the Kishenehn Formation is currently undergoing organic diagenesis. (Edited author abstract) 45 refs.

**077408 APPLICATION OF METALLOPORPHYRIN BIOMARKERS AS PETROLEUM MATURITY INDICATORS: THE IMPORTANCE OF QUANTIFICATION.** The parameters derived from analyses of vanadyl tetraporphyrins in a suite of con-familial (single-source) oils from the Big Horn Basin were found to reflect thermal stress and to correlate well with the bulk maturity parameters, except in one case (i.e. Manderson). Interestingly, the low vanadyl porphyrin concentration in Manderson (10  $\mu\text{g/g}$ ) was consistent with that expected of a quite mature petroleum rather than one of low maturity as indicated by the biomarker profile. Hence, it is argued that the Manderson porphyrins are not representative of the major portion of this petroleum, but rather of a minor amount (ca 5-10%) of less mature petroleum or bitumen picked up during migration to or in the current reservoir. It is concluded that, in general, reliability of biomarker based ratio parameters must be considered contingent on occurrence in expected concentrations and concurrence with bulk petroleum parameters. (Author abstract) 44 refs.

**077409 SURVEY OF HYDROTHERMALLY-GENERATED PETROLEUMS FROM THE GUAYMAS BASIN SPREADING CENTER.** The Guaymas Basin spreading center and hydrothermal system are generating an assortment of petroleum-like bitumens by pyrolysis of organic matter in the overlying unconsolidated sediments. Samples collected by D.S.V. Alvin from hydrothermal fields in the Southern Trough exhibit large variations in the quantities and character of the solvent-soluble organic materials. Various pyrolytic regimes combined with fluctuating thermal gradients and migration velocities may impart a compositional fractionation, possibly by differential gaseous solubilization and hydrodynamic alteration of the multicomponent fluids. The data suggest that differential condensation/solidification, biodegradation, and water-washing cause selective removal of components at the seabed. Many hydrothermal oils are unlike normal reservoir petroleum, because they contain significant concentrations of polar material, due to their rapid genesis and transport and probable solubilization or advection of polar, immature components. The biomarker distributions confirm high-temperature pyrolysis at depth with variable entrainment of less thermally-mature bitumens during transport. (Edited author abstract) 63 refs.

**077410 NON-HYDROCARBONS OF SIGNIFICANCE IN PETROLEUM EXPLORATION: VOLATILE FATTY ACIDS AND NONHYDROCARBON GASES.** Nonhydrocarbon gas species ( $\text{CO}_2$ ,  $\text{N}_2$ ,  $\text{H}_2$ ) are locally important in exploration for gas, and there is a growing body of evidence that acid water originating in shales materially affects the diagenesis of nearby sandstones. These gases have been studied by analyzing the products of closed-vessel hydrous pyrolysis of known petroleum source rocks, and comparing the results with

field observations. Alteration of petroleum source rocks at temperatures  $>250^\circ\text{C}$  yields a significant amount of nonhydrocarbon components. Ethanoate and higher acid anions are liberated in substantial quantities; the yield appears to be related to the oxygen content of the sedimentary organic matter present. The nonhydrocarbon gases  $\text{CO}_2$ ,  $\text{H}_2$  and  $\text{N}_2$  are frequently the dominant gaseous products from hydrous pyrolysis: in the natural environment the same rock sequences at a higher maturity preferentially generate hydrocarbon gases - mainly methane. This discrepancy may be attributed to reaction and phase thermodynamic effects between laboratory and natural systems, behavior that has important implications in the prediction of gas generation and composition in nature by source rock pyrolysis in the laboratory. (Author abstract) 21 refs.

**077411 MODEL FOR THE DETERMINATION OF WATER SATURATION FROM DIELECTRIC PERMITTIVITY MEASUREMENTS.** The dielectric permittivity of a saturated formation is controlled mainly by the amount of water present in the pores; thus, the porosity calculated from the dielectric permittivity is related to the water-filled porosity. The percentage of water present in the pore space is the ratio of water-filled porosity to total porosity. Because the geometrical distribution of the water in the pores changes with water saturation, a direct comparison of the calculated water-filled porosity from dielectric mixing laws to the total porosity is not always a good estimate of water saturation. A more reliable prediction method is to relate the water saturation to the porosity ratio using a saturation exponent analogous to the saturation exponent in Archie's water saturation equation. An equation using an exponent to relate water saturation to the water-filled porosity has been developed using the Hanai-Bruggeman equation to determine the water-filled porosity. The water saturation equation is analogous to, and reduces to, Archie's saturation equation when the conductivity of the rock dominates the electrical response. The magnitude of the exponent varies between formations and can be determined from laboratory measurements. Laboratory measurements on core samples show a high correlation between the water saturation and the ratio of calculated water-filled porosity to total porosity. An approximate relationship between the dielectric saturation exponent and Archie's saturation exponent has been derived and verified. (Author abstract) 12 refs.

**077412 EFFECT OF THE THERMODYNAMIC PORE WATER PRESSURE GRADIENT ON GEOTHERMAL GRADIENTS AND WATER MINERALIZATION IN PETROLIFEROUS BASINS.** The considerable changes of geothermal gradients and mineralization of formation waters often observed in lithologically homogeneous series of sedimentary basins with ellipsoidal or stagnating water pressure conditions are explained by the effect of the convective heat transfer by the downcoming water filtration with a lowering of the average annual paleotemperature on the surface. The downcoming filtration arises in densely packed water-saturated rocks under the effect of the thermodynamic pore water pressure gradient. (Translated author abstract) 6 refs. In Russian.

**077415 DETERMINATION OF LITHOLOGY FROM WELL LOGS BY STATISTICAL ANALYSIS.** This paper presents a method of predicting lithology by statistical analysis of wireline log measurements with calibration to a core lithology standard. Although an example of the technique applied to the Shublik formation of the Prudhoe Bay area, North Slope, AK, is developed and presented, the method can be applied to any field where some core has been taken. A lithology standard must be available to calibrate against during development of a log model of lithology. For the Shublik, the core available provided an excellent sample of the total formation. Using the statistical technique of discriminant analysis, we were able to evaluate a number of log models and to choose the most appropriate one. (Edited author abstract) 8 refs.

**077416 REGIONAL CAPROCK-DESTROYING DOLomite ON THE MIDDLE JURASSIC TO EARLY CRETACEOUS ARABIAN SHELF.** Massive, stratigraphically discordant dolomite occurs on the late Mesozoic Arabian Shelf in the northern portion of Aramco's main producing area. The dolomite is associated with solution-collapse of anhydrite seals and with enhancement of porosity and permeability in tight limestone seals within the region. By destroying regional caprocks, dolomitization has had an adverse effect on oil accumulation. The spatial distribution of this regional dolomite was mapped with wireline log and core data. Geochemical and fluid-inclusion analyses indicate that the dolomite formed from hot saline brines that were first expelled from halite-bearing evaporites, and then migrated into Arabian Shelf carbonates during burial. (Author abstract) 18 refs.

**077417 EVOLUTION DIAGRAM OF KEROGEN STRUCTURE IN THE PROCESS OF HYDROCARBON FORMATION.** It has been established that kerogen, the insoluble organic material in source rocks, is the principal source matrix for hydrocarbon generation. The authors have studied some kerogens which are of different types and maturities. Their IR data are marked on a ternary diagram which takes the relative percentages of 1460  $\text{cm}^{-1}$ , 1600  $\text{cm}^{-1}$ , and 1710  $\text{cm}^{-1}$  as its three vertices. Thus the diagram, which is discussed in this paper, shows the evolution of kerogen structure and composition.

**077418 MODEL OF THE STRUCTURE OF AND THE EFFECTIVE THERMAL CONDUCTIVITY OF A BAZHENOV SUITE.** One of the promising oil fields in the Soviet Union is the deposits of the Berias-Volga stage of Western Siberia. They consist of nontraditional

rock reservoirs, called a Bazhenov suite. A Bazhenov suite consists of mudstone formations, which were for a long time believed to be fluid supports. A model is proposed for the structure of a Bazhenov suite. The relationship between the structure (porosity of emptiness, oil content) and the thermophysical properties of the rock is found. The characteristics obtained are checked under laboratory conditions and then extrapolated to reservoir conditions. 7 refs.

Dul'nev, G.N. (Leningrad Inst of Precision Mechanics & Optics, USSR); Dorofeeva, T.V.; Volkov, D.P.; Muratova, B.L. *J Eng Phys* v 52 n 1 Jan 1987 p 87-94.

**077419 THERMAL HISTORY OF SEDIMENTARY BASINS, MATURATION INDICES, AND KINETICS OF OIL AND GAS GENERATION.** No measurable parameter can be directly converted to paleotemperature. Maturation indices such as vitrinite reflectance,  $T_{\text{max}}$  from Rock-Eval pyrolysis, spore coloration, Thermal Alteration Index (TAI), or concentration of biological markers offer an indirect approach. All these indices are a function of the thermal history through rather complex kinetics, frequently influenced by the type of organic matter. Their significance and validity are reviewed. Kinetics of kerogen decomposition controls the amount and composition of hydrocarbons generated. Kinetic models, based on a specific calibration made on actual source rock samples, can simulate the evolution of all types of organic matter and can provide a quantitative evaluation of oil and gas generated. Examples from the Jurassic source rocks of the Paris basin, Monterey Formation of California, Green River shales of Utah, Paleozoic source beds of the Algerian Sahara, and Miocene rocks of the Manhattan Delta, Indonesia, illustrate various aspects of the discussion. (Edited author abstract) 80 refs.

Tissot, B.P. (Inst Francais du Petrole, Rueil-Malmaison, Fr); Pelet, R.; Ungerer, Ph. *AAPG Bull* v 71 n 12 Dec 1987 p 1445-1466.

**077420 THERMODYNAMIC SEALS OF OIL AND GAS DEPOSITS.** It is argued that, following a modification of certain thermodynamic conditions of rocks, the role of regional seals may be played by light microfissured rocks, e.g. limestones. In this case, the floating up of oil or gas is prevented by the negative thermodynamic pressure gradient of pore water (TPG). This gradient arises in poorly interconnected pores as a result of nonuniform thermal compression of the formation water following a drop in rock temperature. Some examples of such seals are presented. In Russian. 6 refs.

Dobrynin, V.M. *Geol Nefti Gaza* n 4 Apr 1987 p 9-16.

**077421 REVIEW OF THE CRETACEOUS FORMATIONS IN THE ARABIAN PENINSULA AND GULF: PART II. MID-CRETACEOUS (WASIA GROUP) STRATIGRAPHY AND PALEOGEOGRAPHY.** The stratigraphic sequence of the 'Middle' Cretaceous Wasia Group in the Arabian Gulf, and the terminology used, is reviewed. Type sections and synonymy are established for the succession in the United Arab Emirates. An historical introduction provides a key to the understanding of the varied formational and member names in current use. Facies distribution maps show that shallow-water, predominantly carbonate, belts extend across the whole region. Two plastic-carbonate cycles are apparent in the northeastern part of the Gulf, the lower Nahr Umr-Maaddud cycle and an upper Wara-Mishrif cycle. The upper cycle is poorly defined in the southeastern Gulf, and in the Abu Dhabi region a zone of carbonate build-up surrounds a slightly deeper intracratonic basin which developed in Late Albian-Early Cenomanian time. (Author abstract) Refs.

**077422 THEORETICAL ASPECTS OF CAP-ROCK AND FAULT SEALS FOR SINGLE- AND TWO-PHASE HYDROCARBON COLUMNS.**

Cap-rock seals can be divided genetically into those that fail by leakage (membrane seals) and those whose capillary entry pressures are so high that seal failure preferentially occurs by fracturing and/or wedging open of faults (hydraulic seals). A given membrane seal can trap a larger oil column than gas column at shallow depths, but below a critical depth (interval), gas is more easily sealed than oil. Fault-related seals are effectively analogous to membrane cap-rocks which have tilted to the angle of the fault plane. The membrane sealing theory developed assumes that all reservoirs and seals are water-wet and no hydrodynamic flow exists. The conclusions on membrane seal capacity place constraints on the migration efficiency of gas along low-permeability paths at depth where fracturing, wedging open of faults and/or diffusion process may be more important. The developed seal theory and pressure/depth profile concepts are applied to a series of development geological problems. Additional aspects of the subject are discussed. 38 refs.

Watts, N.L. (Shell Int Petroleum Maatschappij BV, The Hague, Neth). *Mar Pet Geol* v 4 n 4 Nov 1987 p 274-307.

**077423 OPTICAL PROPERTIES OF SCOECODONTS AND THEIR USE AS INDICATORS OF THERMAL MATURITY.** Dispersion of reflectances in air and oil between 400 and 700 nm of a suite of scoecodonts concentrate with known Conodont Alteration Index was determined using a reflected light microscope. Refractive and absorptive indices of these scoecodonts were calculated using their determined reflectances. Morphologically, scoecodonts in carbonate show similar granular morphology to that of graptolites. Fine structural details of scoecodonts can be observed under reflected light. Reflectances, refractive and absorptive indices of scoecodonts at 546 nm increase with increase of the Conodont Alteration Index, indicating that these properties of scoecodonts can be used to determine the maturity of sediments. (Edited author abstract) 21 refs.

Goodarzi, F. (Inst of Sedimentary & Petroleum Geology, Calgary, Alberta, Can); Higgins, A.C. *Mar Pet Geol* v 4 n 4 Nov 1987 p 353-359.

**077424 PRECAMBRIAN AS A HYDROCARBON EXPLORATION TARGET.** As recently as 1950 it was generally accepted that sedimentary rock of Precambrian age located within basins, geosynclines, and platforms could not contain hydrocarbon deposits. The absence of pre-Paleozoic Era life and the lack of reservoir rock characteristics in these Precambrian rock columns were the most often presented reasons why Precambrian terranes should be ignored by the petroleum geologist. Within the past three decades evidence for varied forms of life has been discovered in sedimentary rock as old as 3.6 Ga. Simultaneously many Precambrian rock columns have been recognized as possessing excellent reservoir characteristics. With the discovery of commercial deposits of indigenous Precambrian-age hydrocarbons, sedimentary rock deposited throughout the world during this early chapter in earth history is being analyzed by the oil and gas industry. (Author abstract)

Dickes, Albert B. *Geosci Wis* v 11 Sept 1986 p 5-7.

**077425 WORLDWIDE DISTRIBUTION OF PRECAMBRIAN HYDROCARBON DEPOSITS.** Prior to the 1960s a minor amount of 'Precambrian' production was known. These fields normally were created by hydrocarbons derived from Phanerozoic sources migrating into fractured Precambrian igneous rock because of favorable structural associations. Since the 1960s, however, at least a dozen oil and gas fields, several of considerable size, have been discovered in Precambrian reservoir rock, the oil of which was supplied from Precambrian source strata. Such relationships have been made or reported in the East Siberian Platform and the Ural-Volga regions of the USSR, the Amadeus Basin of

Australia, the Sichean and Bohai Bay Basins of China, and the Montana and Lake Superior areas of the United States. (Edited author abstract)

Dickas, Albert B. *Geosci Wis* v 11 Sept 1986 p 8-13.

**077426 PROBLEM OF OIL AND GAS POTENTIAL IN REGIONAL OVERTHRUST ZONES.** A number of regional overthrust zones in the USSR and other regions of the world are considered for their oil and gas-bearing potential. It is argued that the most promising are overthrust rocks situated between the main overthrust planes as well as the natural reservoirs formed in the post-thrust phase. New tasks for regional geophysical explorations are pointed out. Overthrusts whose structures contain deposits of barium of ancient passive forges transformed in the course of orogenesis should be explored in the first place. It is recommended that a computer program be worked out by the year 2000 to assist in modeling the structure of areas with petroleum potential. In Russian. 15 refs.

**077427 LA MIGRATION DES HYDROCARBURES DANS LES BASSINS SEDIMENTAIRES: ASPECTS GEOLOGIQUES ET GEOCHIMIQUES.** [Migration of Hydrocarbons in Sedimentary Basins: Geological and Geochemical Aspects]. Oil migration toward reservoirs and traps, and especially its expulsion from the source rock where it was formed (primary migration), has remained one of the least understood problems in petroleum geology. The displacement of oil and gas occurs in a separate hydrocarbon phase. Water, which is often considered as the vehicle for oil during migration, effectively plays a negative role. Water saturation must have been sufficiently diminished (by expulsion) and hydrocarbon saturation must be sufficiently increased (by generation from kerogen) for the flow of a hydrocarbon phase to become possible. The driving force for this expulsion is the pressure gradient. A rise in pressure in the pore volume of source rocks results from three causes (the sedimentary load, the formation of hydrocarbons, and the thermal expansion of water). Microfracturing, which occurs when the internal pressure of fluids exceeds the mechanical strength of the rock, may play an important role. Among the consequences of migration, mention can be made of the possibility of oil/source-rock correlation, the lower content of heavy products in reservoirs than in source rocks, and the role often played by a displacement in which liquid and gaseous hydrocarbons form a single phase that migrates while progressively leaving the heavier fractions behind it. (Edited author abstract) 41 refs. In French.

Tissot, B.P. (Inst Francais du Pétrole, Rueil-Malmaison, Fr). *Rev Inst Fr Pet* v 43 n 2 Mar-Apr 1988 p 143-153.

**077428 MODEL OF SECONDARY HYDROCARBON MIGRATION AS A BUOYANCY-DRIVEN SEPARATE PHASE FLOW.** A mathematical model of secondary migration is described which permits the prediction of hydrocarbon migration and accumulation patterns in a sedimentary basin if source rock expulsion rates and geometrical and hydraulic properties of major carrier systems are known through geological time. In this model, secondary migration is treated as buoyancy-driven segregated flow of hydrocarbons in hydrostatic aquifers. Lateral updip migration is conceived as a Boussinesq-type free-surface flow with source and sink terms representing supply from source rocks and leakage through cap rocks and faults. This permits a two-dimensional map-view mathematical description of a three-dimensional time-dependent secondary migration (Edited author abstract) 17 refs.

Lehner, F.K. (Koninklijke/Shell Exploratie en Productie Lab, Rijswijk, Neth); Marsal, D.; Hermans, L.; van Kuik, A. *Rev Inst Fr Pet* v 43 n 2 Mar-Apr 1988 p 155-164.

**077429 FLUID FLOW IN LOW PERMEABLE,**

**POROUS MEDIA.** The author presents a methodology for pre-drill pressure prediction system using seismic velocity analysis. This is followed by a simple model of shale compaction as a source of geopressing. The model includes a time and temperature dependent shale compaction law to account for shale dehydration and the smectite to illite transformation. A major conclusion is that geohistory based models, with reasonable control or notions about ranges of geologically accepted parameters such as burial rates and temperature gradients, can predict reliable pre-drill estimates of pressure, stresses and seismic parameters (for example, porosity and velocity). Such information, when calibrated with available well control and integrated with sequence stratigraphic results, can provide a guide to high grade prospects for hydrocarbon detection prior to drill and assist in safety of operation in a geopressed environment. 23 refs.

**077430 RELATIONS ENTRE LES TYPES DE DEPOTS EVAPORITQUES ET LA PRESENCE DE COUCHES RICHES EN MATIERE ORGANIQUE (ROCHES-MERES POTENTIELLES).** [Relationship Between Different Types of Evaporitic Deposits and the Occurrence of Organic-Rich Layers (Potential Source Rocks)]. The fertility of saline waters has been confirmed by studies of salterns in the western Mediterranean. The effectiveness of stratified water bodies for the preservation of organic matter originally produced in photic and oxygenated water is brought out. In shelf (or epicritic) evaporites, where the segregation of salinities and deposits has been synchronous and lateral, the water depth must have been shallow hence unsuitable for the formation of stratified water bodies and their geological duration. In basin-center evaporites, the deposits are attributed to a succession of phases of increasing salinity in time. The third type of evaporitic deposits is represented by basin-margin evaporites. In such a system, the basin center remains starved for long periods of time. The filling of the central part by basin-center evaporites may be a brief episode and may result in the disappearance of the basin. The shelf evaporites spreading on both the former basin area and the former marginal shelves may be the start of new sedimentary cycle without any connection to the past. 56 refs. In French.

**077431 SIMPLE ANALYSIS OF PRIMARY OIL MIGRATION THROUGH OIL-PROPAGATED FRACTURES.** The following conditions are necessary for oil-induced fracture propagation: (a) Organic matter is concentrated into discrete, isolated flakes. If kerogen is finely disseminated, oil-induced fracture propagation is not possible. (b) Kerogen flakes are thin and elongate with a large length to thickness ratio. The length of a kerogen flake must be 6 mm, if it is 0.1 mm thick. (c) Kerogen does not acquire permeability until a small amount of oil is generated. (d) The oil-source rock permeability is not more than that of a compact shale or argillaceous limestone. Oil-generation may cause existent flaws in oil-source rocks to propagate and form a fracture network which acts as a pathway for primary oil-migration. However, before a definite conclusion can be reached, further study is necessary of the relationship between the kerogen size distribution and oil expulsion efficiency of source rocks, and the permeability behaviour of kerogen flakes during source rock maturation. (Edited author abstract) 11 refs.

**077432 TRIANGULATION: MATHEMATICALLY WELL-DEFINED TECHNIQUE FOR CONSTRUCTING GEOLOGIC MAPS.** Special circumstances arise which require the construction of geologic maps without subjective bias and according to a prescribed set of mathematical rules. This article describes triangulation, a mathematically well-defined collection of rules for the manual construction of geologic maps. Given only control

points and a region defined by a closed polygonal boundary, triangulation defines uniquely a continuous surface throughout the bounded region, has no discontinuities, and honors each control point. The map construction requires only a pen, ruler, and hand calculator. Map contours are drawn as straight line segments joining interpolated contour control points and control points of the same value. These contours follow a surface of linked triangular facets (planes) whose intersections and attitudes are defined by the control point locations, their values, and the polygonal boundary.

**077434 PATTERNS OF PERMEABILITY IN EOLIAN DEPOSITS: PAGE SANDSTONE (JURASSIC), NORTHEASTERN ARIZONA.** One of the most important aspects of this study is the correlation of qualitative geologic descriptions with quantitative variables such as permeability. About 2,000 measurements were made with a field minipermeameter on an outcrop of the Page sandstone. These data show that three distinct permeability modes directly relate to the different stratification types. Permeability exhibits two components of variation: a structural or systematic component and a random or noise component. In this context, the structural component may be correlated to identifiable geologic processes, whereas the random component covers all unexplained variations. These definitions, however, are entirely scale dependent. By decreasing the scale of measurement, structure is revealed in the random variation. This scale dependence is evident in the subject outcrop and, using several statistical tools, we are able to illustrate the "nested" nature of the spatial variation in permeability. The work is pertinent to enhanced recovery. (Edited author abstract) 20 Refs.

**077436 APPLICATION OF AROMATIC COMPOUNDS AS MATURITY INDICATORS IN SOURCE ROCKS AND CRUDE OILS.** Generally, these indicators rely either on an increase with maturity in the degree of alkylation of a given parent compound or a shift in the isomer distribution of alkyl-aromatic homologues towards thermally more stable isomers. A combination of both concepts in the Methylphenanthrene Index (MPI) resulted in an excellent maturity parameter, as demonstrated for rock extracts by an improved correla-

tion with mean vitrinite reflectance ( $R_m$ ) between 0.65 and 1.4%, i.e., in the zone of oil formation. Organic facies effects should be taken into account in the interpretation of aromatic distributions of such source rocks and related crude oils. Aromatic maturity parameters are particularly useful in the maturity evaluation of post-mature crude oils and condensates. In contrast to biological markers, substantially higher concentrations of the key alkyl-aromatics persist at elevated maturation levels. Additional aspects of the subject are discussed. (Edited author abstract). 31 Refs.

**077437 GAS-CONDENSATE MIGRATION AND OIL FRACTIONATION IN DELTAIC SYSTEMS.** The term evaporative fractionation is proposed to describe several phenomena involved in the secondary alteration of reservoir oil. Firstly, it is suggested that oil is frequently partially vaporized in the reservoir; secondly, that gas, bearing substantial portions of the oil in solution, is conducted along faults to form independent gas-condensate accumulations; thirdly, that residual oils formed in this fashion bear internal evidence of fractionation. In addition to the conspicuous loss of light ends, there is an increase in the content of light aromatic and naphthenic hydrocarbons relative to paraffins in the residual oil. Evaporative fractionation effects are recognized for the first time in the distillation and physical property data of US Bureau of Mines Routine Method Oil Analyses. Experimental evidence shows that partial vaporization results in enhanced levels of light aromatic hydrocarbons in residual oils. Additional aspects of the subject are discussed. **077438 SIMPLE ANALYSIS OF OIL-INDUCED FRACTURING IN SEDIMENTARY ROCKS.** Geometric form of kerosen patches control oil-induced fracturing in impermeable source rocks. Thin elongate kerosen flakes cause lateral fracturing. Kerosen has to occur in spherical or cylindrical forms to induce vertical fractures. If length to width ratio of kerosen flakes is sufficiently large, then lateral fractures are definitely initiated during oil generation in impermeable source rock. Oil and rock compressibilities and lateral to vertical stress ratio are decisive factors in vertical fracturing in impermeable rocks. When the source rock is permeable, then the rate of oil seepage from kerosen into the surrounding rock is crucial in fracture initiation. Oil-induced fractures cannot form unless permeability, and hence rate of oil seepage from kerosen into the surrounding rock, is non-existent or negligible. Most source rocks have some permeability. Therefore, oil-induced fracture initiation should be a rare phenomenon. (Edited author abstract). 12 Refs.

**077439 ORIGIN OF PETROLEUM.** The theory of the direct origin of petroleum from living organisms and of proto petroleum origin in the theory of organic origin has declined recently because it is difficult to explain their primary migrations. As a result, the theory of kerosen origin has been put forward. Kerosen is insoluble organic matter, and contains over 90 percent of sedimentary organic matter. Moreover, kerosen generates hydrocarbons by thermal distillation. Petroleum source rocks and reservoir rocks are bound to muddy rocks having abundant organic matter, and to sandstones or carbonates having high porosity and permeability, respectively. Commercial oils were generated by thermal transformation of the kerosen in source rocks, and then migrated and accumulated in reservoir rocks. The mechanism of the primary migration of oils from kerosen is explained by the oil phase or gas phase transport. Recently, immature oils have been found in many fields. In this paper, the possibility of the origin of immature oils is discussed, but a detailed study of this problem should be made in the future. (Edited author abstract). 29 Refs. In Japanese.

**077440 OCCURRENCE OF PETROLEUM.** The world's oil is found in marine sediments of sedimentary basins. Oil accumulations are usually found in the areas of the most intimate association of source and reservoir facies. Petroleum is found in rocks from most geologic ages and all over the world, but it is most abundant in sediments younger than the Jurassic and in the Middle East and Gulf of Mexico areas. Since an increase in continental shelves and restricted basins occurred when the continents split during the Jurassic, older oil fields became increasingly destroyed and the rate of sediment formation has changed over geologic time. As a result, giant oil fields are distributed in the Middle East and Gulf of Mexico where they were located in shallow sea areas during the Jurassic-Cretaceous. (Edited author abstract). 8 Refs. In Japanese.

**077442 RESERVOIR HETEROGENEITIES IN FLUVIAL SANDSTONES: LESSON FROM OUTCROP STUDIES.** Outcrop studies provide information on typical geometries and size ranges for input into reservoir model studies. Macroforms are complex, compound bars (e.g., point bars) bounded by fourth-order surfaces. Accretionary phases may be separated by internal, low-angle third-order surfaces. Fifth-order surfaces define major channel bodies, ranging from ribbon to sheetlike in geometry. Sheet sandstones may be mappable using closely spaced well data, but ribbon sandstones are difficult to correlate except in the most well-developed field. Three-dimensional seismic is a powerful new tool for mapping fifth-order surfaces. The largest scale represents units at the member or submember level, bounded by sixth-order surfaces. These units are mappable using conventional wireline log correlation. The area of a shale bed depends on the scale of the lithosome with which it is associated. (Edited author abstract). 69 Refs.

**077443 CHLORINE ISOTOPE DISTRIBUTION IN FORMATION WATERS, TEXAS AND LOUISIANA.** Theoretically, the chlorine isotope ratio,  $^{37}\text{Cl}/^{35}\text{Cl}$ , can aid in identifying chloride sources and in distinguishing chloride-transport mechanisms among formation waters if ratio differences exist among samples. We measured the chlorine ratios of 18 formation-water samples from oil fields along the Texas-Louisiana Gulf Coast representing depths between 2,016 and 4,267 m. Chloride concentrations of samples ranged from 4 to 94.874 g/L, the chlorine ratios ranged from -1.24 to 0.58 percent (with respect to standard mean ocean chloride or SMOC, precision 0.12 percent). We conclude that significant chlorine isotope ratio differences exist among formation waters and between the waters and potential sources in the Gulf Coast region, and that the chlorine ratio will be a valuable tool in interpreting chloride geochemistry in this region. (Edited author abstract). 22 Refs.

**077444 DETERMINATION OF SUBSURFACE DISTANCE BETWEEN VERTICAL PARALLEL NATURAL FRACTURES BASED ON CORE DATA.**

A simplified method is presented to estimate subsurface distance between vertical parallel fractures based on core analysis and the binomial theorem. The geologic model used in this paper is identical to the one presented by Narr and Lerche in 1984. Required input data includes core diameter (D), thickness of each bed intercepted by the core (T), angle between core axis and fractures ( $\beta$ ), and angle between core axis and bedding ( $\theta$ ). The method is corroborated with the use of outcrop data previously published by Narr and Lerche in 1984. The approach is illustrated with a step-by-step example, which easily can be reproduced with a hand-held calculator by the practicing geologist. (Author abstract). 5 Refs.

**077445 TO TACKLE THE DECONVOLUTION PROBLEM - A POWERFUL METHOD BASED ON MORE GEOLOGICAL HYPOTHESES.** The approach described in this paper abandons the usual hypothesis (white reflectivity spectra) made by deconvolution methods and employs as alternative information the lateral redundancies which are always present on a seismic section. Our method first estimates the location of high amplitude reflectors with good lateral continuity, by means of an elegant automatic picking program. Based on these locations, a generalized inversion can be used to yield the wavelet emitted by the source, and the amplitude of the main reflection coefficients simultaneously for each trace. All the reflection coefficients are then estimated using the amplitudes and the wavelets computed previously. The various stages of this method which is called Deconvolution-Inversion are illustrated in the paper by means of both synthetic and real examples. (Edited author abstract)

**077446 DEPOSITIONAL MODEL FOR THE DUPUY MEMBER AND THE BARROW GROUP IN THE BARROW SUB-BASIN, NORTHWESTERN AUSTRALIA.** A detailed sedimentological study of the Dupuy Member and the Barrow Group has resulted in a regional model for the deposition of these Upper Jurassic to Lower Cretaceous reservoir sequences in the Barrow Sub-basin. The Dupuy Member is interpreted as a prograding offshore slope sequence of turbidite sandstones and debris flows, which built laterally into the Barrow Sub-basin from along its eastern margin. Structural growth of the Barrow Island anticline took place during deltaic deposition and caused anomalous relationships between foresets and bottomsets under the north of Barrow Island. Known hydrocarbon accumulations and common shows in the Dupuy Member and the Barrow Group make these sequences attractive exploration targets. (Edited author abstract) 12 refs.

Alabama

**077447 ENVIRONMENTS OF DEPOSITION AND PETROLEUM GEOLOGY OF TUSCALOOSA GROUP (UPPER CRETACEOUS), SOUTH CARLTON AND POLLARD FIELDS, SOUTHWESTERN ALABAMA.** In southwestern Alabama, the lower Tuscaloosa Group (Upper Cretaceous) consists of two informally defined units, the Massive and Pilot sand intervals. The Massive sand interval accumulated principally as sands in a wave-dominated, high-destructive delta system. The Pilot sand interval, which overlies the Massive sand interval, accumulated as shelf sands and clays during a marine transgression. The Pilot sand interval is overlain by a marine claystone (Marine shale) containing a diverse faunal assemblage of macroinvertebrates, including ammonites, inoceramids and other bivalves, and a rich microfossil assemblage of planktonic foraminifera and calcareous microfossils. Petroleum traps in the Tuscaloosa are structural traps involving salt anticlines (South

Carlton field) and extensional fault traps associated with salt movement (Pollard field). Although Tuscaloosa marine claystones contain significant amounts of organic carbon, these rocks are thermally too immature to be the petroleum source rocks for the Tuscaloosa crude oils in South Carlton and Pollard fields. (Edited author abstract) 40 refs.

## Alaska

**077448 EVOLUTION AND PETROLEUM GEOLOGY OF AMLIA AND AMUKTA INTRA-ARC SUMMIT BASINS, ALEUTIAN RIDGE.** Amlia and Amukta Basins are the largest of many intra-arc basins formed in late Cenozoic time along the crest of the Aleutian Arc. Both basins are grabens filled with 2-5 km of arc-derived sediment. Two groups of normal faults occur: major boundary faults common to both basins and 'intra-basin' faults that arise primarily from arc-parallel extension of the arc. Although, the hydrocarbon potential of Amlia and Amukta Basins is difficult to assess based on existing data, regional considerations imply that an adequate thermal history conducive to hydrocarbon generation has prevailed during the past 6-5 my. Additional aspects of the subject are discussed. 42 refs.

## Alberta

**077449 GEOLOGICAL AND SEISMIC EVALUATION OF A LOWER MANNVILLE VALLEY SYSTEM; ALDERSON PROSPECT, ROLLING HILLS, SOUTHEASTERN ALBERTA.** A Lower Mannville valley complex cut into Jurassic and Mississippian strata in southeastern Alberta was identified on a conventional seismic section. Sediments adjacent to the valley are interpreted as contemporaneous levee and splay deposits of a channel that occupied the valley, whereas the muddy sandstones within the channel represent either a fine grained point bar, or an abandoned channel-fill deposit. In the latter case, coarse grained, sandy, point bar deposits can be expected to occur elsewhere in the channel system. Oil is trapped in crevasse splay deposits draped over a local Mississippian high, but not in the valley because of poor reservoir quality of the channel sandstones. It is proposed here that reflection above Lower Manhattan valleys can provide a means of determining the type of valley fill. (Edited author abstract) Refs.

**077450 COMPUTERIZED DATABASE APPLICATIONS TO THE LOWER CRETACEOUS MANNVILLE GROUP OF THE LLOYDMINSTER AREA, CANADA: PRINCIPLES, CONCEPTS AND APPROACHES.** A computerized system for the acquisition, storage and retrieval of subsurface data applicable to clastic sequences of the Lloydminster area of western Canada is described. The system incorporates stratigraphic, lithologic and fluid data obtained from well logs. The data base is comprehensive enough to permit that examination of lithologic sequences with respect to both external geometry and internal heterogeneities. Data are gathered over large stratigraphic intervals, but at a detail near the vertical lithologic resolution of the well logs employed. Information for stratigraphic markers contains a factor related to their ease of correlation, and all correlatable markers are assumed to represent chronostratigraphic surfaces. A complete suite of lithologic types is systematically obtained from spontaneous potential well log traces. Additional aspects of the subject are discussed. (Edited author abstract) 4 refs.

## Analysis

**077452 PREDICTIVE ISOPACH MAPPING OF GAS SANDS FROM SEISMIC IMPEDANCE: MODELED AND EMPIRICAL CASES FROM SHIP SHOAL BLOCK 134 FIELD.** Gulf of Mexico Miocene through Holocene stratigraphy exhibits general physical properties conducive to detailed geophysical investigation. Reflected seismic energy displayed as acoustic impedance sections are used to produce pseudo 'net pay' isopach maps, which are used to predict gas sand thickness, gas distribution, and gas reserves. The techniques and concepts used in this form of geologic analysis are demonstrated in the rediscovery and development of the Ship Shoal Block 134 gas field of offshore Louisiana. Using the properties of amplitude, acoustic impedance, and reflected energy to produce net pay isopach maps has led to 95% successful prediction of gas reserves within this study area and other areas. Additional study results are discussed. (Edited author abstract) 12 refs.

## Antarctica

**077453 PRELIMINARY ASSESSMENT OF THE HYDROCARBON POTENTIAL OF THE LARSEN BASIN, ANTARCTICA.** Upper Jurassic anoxic marine strata, deposited prior to the main phase of arc development, form a rich potential source (T.O.C. up to 3.5%) with both marine and terrestrial kerogens. Arc-derived volcanoclastic sediments of Barremian-Oligocene age form a regressive megasequence. Basal strata represent slope apron and rudaceous submarine fan deposits proximal to the margin; fan conglomerates form lenticular bodies hundreds of meters thick and tens of kilometers across, enveloped in slope-apron mudstones. Late Cretaceous fault reactivation and uplift led to dramatic shallowing of the basin, with deposition of shelf facies. In the Larsen Basin, there is moderate potential for oil generated from Upper Jurassic source rocks and reservoired in Cretaceous and Tertiary sandstones and conglomerates in large stratigraphic or structural traps caused by partial basin inversion during deposition. (Edited author abstract) 82 refs.

## Arkansas

**077454 THRUST CONTROL ON THERMAL MATURITY OF THE FRONTAL OUACHITA MOUNTAINS, CENTRAL ARKANSAS, USA.** Three types of anomalies in thermal maturity exist within the frontal thrust belt of the Ouachita Mountains, Arkansas, USA. The anomalies were documented by combining structural mapping with measurements of vitrinite reflectance; all

samples were obtained from surface exposures. Maturity-inversion occurs along the Y-City Fault, where Jackfork and Johns Valley strata (Lower Pennsylvanian) have been thrust over less-mature sequences of the lower Atoka Formation (Middle Pennsylvanian). An apparent shear-heating aureole is also associated with this important thrust, although the spatial extent of the aureole is limited. When allowances are made for both structural and stratigraphic position, it is found that internal gradients in vitrinite reflectance within individual thrust sheets are abnormally low. These gradients are attributed to tectonic burial. Weak remnants of the primary stratigraphic gradients are retained in most instances, so organic metamorphic reactions evidently failed to equilibrate during thrust loading; rapid unroofing of the thrust belt may have begun even as some faults remained active. Similar patterns of maturation should be expected within other thrust belts where peak burial and heating events were synchronous with deformation. (Edited author abstract) 50 Refs.

**077455 HYDROCARBON POTENTIAL OF THE UPPER JURASSIC/LOWER CRETACEOUS OF THE AUSTRALIAN NW SHELF.** Source-rock richness, timing of hydrocarbon generation, and thicknesses of potential source shales of the Upper Jurassic/Lower Cretaceous section of the Australian NW Shelf have been examined in order to make predictions as to the hydrocarbon potential of the several basins in that region. The result is a rating of four areas potentially productive of liquid hydrocarbons: the Browse Basin, the Malita Graben/NW Bonaparte Gulf Basin, the Rowley Sub-basin, and the Vulcan Sub-basin/Sahul Syncline, respectively. Recent liquid hydrocarbon discoveries in the Vulcan Sub-basin, probably sourced by the Upper Jurassic shales, upgrade all four of these areas, and lead to the conclusion that, overall, drilling results on the NW Shelf have to date not been indicative of its true potential. Therefore, it is recommended that future hydrocarbon 'plays' incorporate the timing of generation as delineated in this study with the timing of structural development in order to improve chances of success, rather than relying on the size of structures alone. (Edited author abstract)

Baird, R.A. (Virginia Polytechnic Inst & State Univ, Blacksburg, VA, USA); Philp, R.P. *J Pet Geol* v 11 n 2 Apr 1988 p 125-140.

**077456 DEPOSITIONAL ENVIRONMENTS AND HYDROCARBON POTENTIAL OF THE EVERGREEN FORMATION, ATP 145P, SURAT BASIN, QUEENSLAND.** Hydrocarbon discoveries in the Jurassic Evergreen Formation along the western shelf of the Surat Basin lie in a northwest-trending structurally controlled belt adjacent to Bridge-operated ATP 145P. Shows and commercial accumulations are generally associated with specific sand/shale ratios, which influence source, reservoir, and seal effectiveness. Proximity to basement and early faults are other favourable factors. Four distinct log facies were calibrated against cuttings and core and interpreted genetically. On the basis of a petrographic study the highest source potential for the Evergreen Formation in ATP 145P is around Spring Grove 1 well. A band of high source potential lies parallel to the deltaic shoreline, in a generally north-south direction. (Edited author abstract) 23 refs.

**077459 HYDROCARBON GENERATION, MIGRATION AND ENTRAPMENT IN THE JACKSON-NACCOWLAH AREA, ATP 259P, SOUTH-WESTERN QUEENSLAND.** The northern part of the Naccowlah Block, situated in the southeastern part of the Authority to Prospect 259P in southwestern Queensland, is a major Eromanga Basin hydrocarbon province. The Hutton Sandstone is the main reservoir but hydrocarbons have been encountered at several levels within the Jurassic-Cretaceous sequence. In contrast, the underlying Cooper Basin sequence is generally unproductive in the Naccowlah Block although gas was discovered in the Permian at Naccowlah South 1. Oil and gas discoveries within the Eromanga Basin sequence are confined to the Naccowlah-Jackson Trend. (Edited author abstract) Refs.

Vincent, P.W. (Vamgas Ltd, Melbourne, Aust); Mortimore, I.R.; McKirdy, D.M. *APEA J* v 25 pt 1 1985, APEA Conf: Tech Pap, Perth, Aust, Mar 24-27 1985 p 62-84.

**077460 TECTONICS OF THE JACKSON-NACCOWLAH AREA, COOPER-EROMANGA BASINS, SOUTHWEST QUEENSLAND, AND THEIR IMPLICATIONS FOR HYDROCARBON ACCUMULATION.** The Naccowlah-Jackson Trend in the Cooper-Eromanga Basins, southwest Queensland, has been the scene of a high hydrocarbon exploration drilling success ratio during the 1980s. The structural trend is mainly the result of sinistral convergent wrenching, which has given rise to a series of major reverse faults and two distinct series of relatively minor parallel and orthogonal basement faults. Structural growth due to wrenching has been responsible for a favourable integration of the components necessary for hydrocarbon generation and accumulation, but also appears to be responsible for crestal faulting which in several cases is interpreted to have led to the escape of hydrocarbons. Two basic oil types (Hutton type and Murta type) are known. (Edited author abstract) 13 refs.

Nelson, A.W. (CSR, Adelaide, Aust). *APEA J* v 25 pt 1 1985, APEA Conf: Tech Pap, Perth, Aust, Mar 24-27 1985 p 85-94.

**077461 REVIEW OF THE HYDROCARBON HABITAT OF THE EASTERN AND CENTRAL BARROW - DAMPIER SUB-BASIN, WESTERN AUSTRALIA.** This paper describes a number of aspects of the petroleum geology and geophysics of the northern Carnarvon Basin resulting from exploration undertaken by second round joint ventures since 1981, mainly in the area surrounding Barrow Island. New techniques applied by the industry over the last few years have enabled a more detailed analysis of exploration areas and basin models. Greatly improved seismic quality (Ramsden, 1984), plus more tightly spaced seismic grids has enabled definition of depositional patterns and facies distributions (Kirk, 1985), while the introduction of new, detailed geochemical techniques has led to a better understanding of likely oil source beds and timing of hydrocarbon expulsion. These factors, in combination with a near doubling of exploration drilling density over the past few years and an increase in the discovery success rates, has led to a more complete understanding of the Carnarvon Basin and its hydrocarbon habitat. 20 refs.

Kopsen, E. (Minora Resources NL); McGann, G. *APEA J* v 25 pt 1 1985, APEA Conf: Tech Pap, Perth, Aust, Mar 24-27 1985 p 154-176.

**077462 RIFT AND DRIFT IN THE DAMPIER SUB-BASIN, A SEISMIC AND STRUCTURAL INTERPRETATION.** Quality improvements in marine reflection seismic data over recent years have led to a better understanding of the relationships between seismic-stratigraphical sequences present in the Dampier Sub-basin and those in adjacent areas. The 'drift-onset' unconformity, which separates the syntectonic rift sequence from the post-tectonic drift sequence, can now be seismically recognised as a single unfaulted surface. The presence of Callovian and Upper Jurassic marine sands on the Rankin Platform shows that the Rankin Platform was in places submerged during Callovian and Upper Jurassic times. (Edited author abstract) 16 refs.

**077463 PETROLEUM GEOLOGY OF THE MERLINLEIGH SUB-BASIN, WESTERN AUSTRALIA.** Esso's recent drilling program in the Merlinleigh Sub-basin, onshore Carnarvon Basin, represents the culmination of the first phase of concerted exploration activity in the area since the WAPET era of the 1960s. The region is unusual among Australian petroleum provinces in having excellent exposures of reservoir, source and seal rocks of Palaeozoic age. While both Esso wells (Burna 1 and Gascoyne 1) failed to encounter hydrocarbons in the primary Wooramel Group play, encouraging potential still exists. The reservoir in the Wooramel Group play is the Early Permian Moogooloo Sandstone, a fluvio-deltaic to nearshore sheet-sand facies with porosities to 23 per cent and permeabilities in excess of 100 millidarcys. Likely hydrocarbon sources are siltstones in the overlying Byro Group. (Edited author abstract) 14 refs.

Percival, I.G. (Esso Australia Ltd, Sydney, Aust); Cooney, P.M. *APEA J* v 25 pt 1 1985, APEA Conf: Tech Pap, Perth, Aust, Mar 24-27 1985 p 190-203.

**077464 SOURCE POTENTIAL OF UPPER TRIASSIC FLUVIO-DELTAIC SYSTEMS OF THE EXMOUTH PLATEAU.** The fluvio-deltaic rocks of the Upper Triassic Mungaroo Formation of the Exmouth Plateau contain abundant organic material in the form of both coal seams and dispersed fragments. Several thousand metres of these sediments lie within the oil generation window but they have commonly not been considered as source rocks for oil because the organic matter is of terrestrial origin. Increasing acceptance of plant material as a source for oil warrants an assessment of the oil generating potential of the Mungaroo Formation. A quantitative assessment of the oil-generating potential of

the organic matter based on maceral composition, vitrinite reflectance and volume of coal and dispersed organic matter was made for a range of time-rock units. On this basis, the Carnian-Ladinian and Carnian sequences have the best source potentials. (Edited author abstract) 22 refs.

**077465 GEOLOGY AND EVOLUTION OF THE SOUTH PEPPER HYDROCARBON ACCUMULATION.** The South Pepper field, discovered in 1982, is located 30 km southwest of Barrow Island in the offshore portion of the Barrow Sub-basin, Western Australia. The oil and gas accumulation occurs in the uppermost sands of the Lower Cretaceous Barrow Group and the overlying low permeability Mardie Greensand Member of the Muderong Shale. The hydrocarbons are trapped in one of several fault closed anticlines which lie on a high trend that includes the North Herald, Pepper and Barrow Island structures. The proposed structural and hydrocarbon migration history fits regional as well as local geological observations for the Barrow Sub-basin. (Edited author abstract) 18 refs.

**077466 EXTENSIONAL BASIN - FORMING STRUCTURES IN BASS STRAIT AND THEIR IMPORTANCE FOR HYDROCARBON EXPLORATION.** The Bass, Gippsland and Otway Basins of south-eastern Australia were initiated by north-northeast to south-southwest lithospheric extension, largely during the Early Cretaceous. The extensional stage was followed by a Late Cretaceous to Pliocene thermal subsidence stage and a late stage of compressional tectonic overprinting. The major extensional structures have had an important influence on all stages of the evolution of these basins. It is contended that a thorough understanding of their extensional framework is an important factor in hydrocarbon exploration of these and other basins. (Edited author abstract) Refs.

## Austria

**077467 ORGANIC GEOCHEMISTRY OF VIENNA BASIN: MODEL FOR HYDROCARBON GENERATION IN OVERTHRUST BELTS.** The Vienna basin is a Tertiary pull-apart basin in the Alpine-Carpathian overthrust belt. Thickness of the sedimentary sequence, including Neogene basin fill, Mesozoic overthrust complex, and Mesozoic autochthonous strata, can exceed 10,000 m (33,000 ft). Source rocks for oil and gas are in the autochthonous Jurassic sequence beneath the overthrust. We can assume that much of the source potential of these rocks was preserved during thrusting and most of the hydrocarbon generation took place after thrusting during Neogene burial. The vertical stacking of hydrocarbon pools indicates predominantly vertical migration through major faults. Results of geochemical studies have influenced exploration strategy in the Vienna basin as well as in the northern Alps and the foreland basin. The Vienna basin could thus be considered a model for hydrocarbon generation in other overthrust belts. (Author abstract). 18 Refs.

**077468 OIL AND GAS GEOLOGICAL ZONING AND REASONABLE COMPLEX OF EXPLORATION AND PROSPECTING IN AZERBAIDZHAN.**

Altogether eight oil and gas bearing regions have been established. They are characterized by different degrees of geological exploration and extraction of the initial oil and gas resources. They are the following ones: Apsheron, Shemakha-Kobystan, Lower Kura, Baku Archipelago, Kirovabad, Evlakh-Agdzhabedy, Kura-Iori interfluvium, and Precaspian-Kuba regions. The most promising area is the Apsheron periclinal trough. Promising areas of the first category are: Baku Archipelago, Lower Kura depression, Evlakh-Agdzhabedy trough, and the Kura-Iori interfluvium. Details on the various promising areas are given. In Russian. 4 refs.

## Bashkiria, USSR

**077469 LOWER PERMIAN CARBONATES - PROMISING OIL EXPLORATION TARGET IN BASHKIRIA.** The main productive levels in the platform part of Bashkiria are the terrigenous-carbonate deposits of the middle and lower part of the Paleozoic sedimentary cover which have been fairly well explored by a great number of deep wells. However, the oil and gas potential of the Lower Permian carbonate strata up to 1000 m thick has not been adequately studied. A purposeful investigation of the petroleum potential of these strata has shown the presence of hydrocarbon deposits at shallow depths. Some recommendations are more intensive explorations in certain specific areas are given. In Russian. 2 refs.

## Canada See OIL SHALE—Canada.

## Caspian Sea

**077470 MECHANISM OF FORMATION OF SOUTH CASPIAN MEGADEPRESSION AND THE MAIN REGULARITIES OF ITS TECTONIC DEVELOPMENT.** Based on an integrated analysis and generalization of the geological and geophysical data on the South Caspian megadepression (SCMD), the mechanism and time of its formation have been clarified. It is shown that the geodynamic situation existing in the SCMD as well as the geophysical fields that characterize it are very similar to those existing in a number of deep water basins of the Alpine-Himalayan folded belt, the formation of which took place as a result of the mantle diapirism which resulted in the tension and destruction of the earth's crust. An attempt is made to single out three stages of rift genesis in the history of the SCMD. The dependence of the geological events taking place in the Cenozoic period within the SCMD on the movements of the lithospheric plates also resulted in the reformation of its structural plan formed earlier. (Translated author abstract) In Russian. 17 refs.

## Chile

**077471 GEOLOGY, GEOMORPHOLOGY, AND PETROLEUM POSSIBILITIES OF THE EL GODO AREA, IQUIQUE, CHILE.** The presence of solid bitumen in the El Godo area of Tarapaca province, northern Chile, has been known for centuries but, from a petroleum viewpoint, the region has been little studied. A major deterrent to exploration has been the presence of volcanic accumulations in the objective section, a marine Jurassic sequence more than 3,000 m thick, which has been intruded by some younger silicic plutons. Objectives older than the Jurassic are unknown but may be present, especially in the deep part of the Jurassic basins and in the offshore. Two basins are present with a total prospective area of about 20,000 sq. kms. They contain shale and carbonate source rocks, shale and evaporite seals, and probable reservoir rocks (carbonates, terrigenous clastics, breccias). Anticlines, formed during the Nevadan orog-

eny, are present. The widespread presence of bitumen in outcrops indicates that oil has been generated. The western basin has thick syndepositional volcanics, and is the less attractive of the two basins. The eastern basin is nearly free of volcanic rocks and is a prime prospect. (Edited author abstract).

## Dating See Also OIL FIELDS—North Sea.

**077472 DETERMINATION OF PALEO HEAT-FLUX FROM FISSION SCAR TRACKS IN APATITE.** Three methods are presented for determining paleo heat flux from fission scar tracks in detrital apatite collected from wells. The three methods invert the present-day fission-track well data along the burial paths of the sedimentary units. The first two methods involve inverting the depth-dependent (a) areal track-number density per gm of uranium and (b) mean track length to obtain an estimate of the temporal dependence of the paleo heat flux. Since these methods tend to overlook short tracks (method (a)), and be biased towards longer tracks (method (b)), they tend to provide paleo heat-flux variations which are too high and too low, respectively. The uncertainty in the determination of paleo heat-flux variation is also quite high, as is shown by using data from two wells: Kambara-1 and Curunga-1 in the NW Canning Basin, Australia. The third method inverts all of the individual distributions of track lengths at each sampled depth in a well. The sensitivity of this method is much higher than methods (a) or (b). In fact, with this method it is possible to determine not only the rate of change of heat flux with time but, for the first time, variations in the direction of change of heat flux, thus making it possible to quantify heating and cooling events, as opposed to just detecting heating or cooling events. (Edited author abstract) Refs.

## East Siberia, USSR

**077473 UPPER LENA VAULT UPLIFT - A NEW PROMISING OBJECT OF GAS POOL EXPLORATION IN ANGARA-LENA OIL AND GAS REGION.** Several parametric and exploratory drillings in the central part of the Angara-Lena oil and gas region and its south-eastern flank (Upper Lena region) have yielded geological data testifying to considerable potentialities of these formations. Gas condensate deposits are likely to be found within the Upper Lena vault which is the main positive structural element of the Angara-Lena bench. The zone of its conjugation with the Pre-Baykal trough is also evaluated positively. In Russian. 4 refs.

Shutov, G.Ya. *Geol Nefti Gaza* n 1 Jan 1987 p 5-8.

## Florida

**077474 SUCCESS AND SENSIBILITY IN SOUTH FLORIDA.** To date, the central and southern portions of the Florida peninsula have supported the discovery and development of a single hydrocarbon trend - that in the Sunniland formation of Early Cretaceous age, which currently produces along a northwest-southeast zone near the updip margins of the South Florida basin. The South Florida basin covers some 50,000 square miles, encompassing the entire southern portion of the peninsula and its shallow westward extension to the Florida Escarpment. Total sedimentary thicknesses within the basin are greater than 15,000 ft and may be as high as 25,000-30,000 ft. A total of 14 fields has been discovered to date in the Sunniland Trend. Estimated oil in place is 260 million bbls, of which approximately 100-120 million bbls are presumed recoverable. A historical and policy overview of the drilling activity in South Florida is followed by a summary of the geologic history of South Florida, structural geology, productive and prospective forma-

tions, and the source rock potential evaluation of the South Florida basin. 99 refs.

## Gulf of Mexico

**077475 EXPLORING THE EASTERN GULF: THE CASE FOR EXPANSION.** A survey of the present-day geologic setting of the Eastern Gulf of Mexico is followed by an overview of the drilling in southwestern Alabama and northwestern Florida. Further chapters present a geotectonic history of the eastern Gulf, structural overview of the eastern Gulf, reservoir intervals of the northeastern Gulf, productivity trends and possibilities in the northeastern Gulf, and the costs and regulations connected with the exploration. 207 refs.

Anon. *Pet Front* v 4 n 2 1987 101p.

**077476 GEOLOGY OF A CONTINENTAL SLOPE OIL SEEP, NORTHERN GULF OF MEXICO.** An oil and gas seep was documented by replicate sampling with piston corer, abundant high-resolution and sparse multi-channel seismic reflection profiling, and chemical and isotopic analyses. The seep occurs on the upper continental slope over a salt ridge interpreted to split and plunge eastward, northeastward, and northward. The relatively shallow diapir over which the seepage occurs is manifested at the surface by a graben in strike section and by a half-graben in dip section. Faulting over the crest is commonly associated with loss of reflected energy or acoustic wipeouts. Most cores taken in wipeouts with prolonged bottom echoes contain oil and gas. The seepage demonstrates the existence of source rocks and maturation at this site. Additional aspects of the subject are discussed. (Edited author abstract) 17 refs.

## Gulf of Suez

**077477 GULF OF SUEZ-NORTHERN RED SEA NEOGENE RIFT: A QUANTITATIVE BASIN ANALYSIS.** Subsidence analysis (backstripping) was carried out on a series of wells from the Gulf of Suez and northern Red Sea region of Egypt in order to examine the interplay between tectonic events, basin subsidence, sedimentation and sea level changes in a young, developing ocean basin and continental margin. Using constraints on chronostratigraphy and paleodepth from various sources combined with stratigraphic and structural information from industry wells and other geophysical sources it has been possible to compile the data necessary to perform geohistory analyses throughout the region. Major subsidence due to crustal thinning began 25 Ma with sedimentation initially occurring in isolated sub-basins. Open marine sedimentation occurred across all structural regimes. The mid-Clysmic tectonic event (16.5 Ma) resulted in structural rearrangement of the rift basin and uplift of the rift shoulders. Rapid subsidence continued as global sea level fell. The quiescence in subsidence combined with a lowered global sea level resulted in the deposition of a thick (up to 4 km) series of evaporites within the central trough of the rift from the middle to latest Miocene. Additional aspects of the subject are discussed. (Edited author abstract). 100 Refs.

## High Temperature Effects

**077478 TEMPERATURES OF OIL AND GAS FORMATION IN THE SUB-SURFACE.** The authors have calibrated a kinetic scheme that describes oil and gas formation using geological samples that have been heated under both natural and laboratory conditions. These equations predict that in the subsurface the influence of time is not great, and that most oil is formed between 100 and 150°C; and most gas between 50 and 220°C. 24 refs.

Illinois See PETROLEUM PROSPECTING—Illinois.

## Iowa

**077479 FOREST CITY BASIN: IS THERE OIL IN THE PALEOZOIC SEDIMENTS?** Between shallow oil production to the south and a deep dry hole to the north there exists a vast area that has only been sparsely tested by drilling to any depth, shallow or deep. The distance between the oil discovery and Amoco's well is 200 miles. The oil discovery to the south and the deep well to the north have created an interest in the area. The area of interest is Southwest Iowa. This article discusses whether the deeper part of the sedimentary Forest City basin contains large accumulations of hydrocarbons, and whether the undrilled shelf area of the Forest City basin contains hydrocarbons in abundance. Data from one reflection seismograph profile suggest there is 20,000 ft of sediments, a thick section of potential oil source rocks, and a large shallow anticline as a possible oil trap. 13 refs.

Miller, George H. *Oil Gas J* v 86 n 16 Apr 18 1988 p 103-104, 106-107, 109.

## Israel

**077480 LATE CENOZOIC THERMAL GRADIENTS IN DEAD SEA TRANSFORM SYSTEM BASINS.** Coal-rank measurements and heat-flow data from three rhomb-shaped grabens along the continental portion of the Dead Sea Transform - the Hula Depression, the Sea of Galilee and the Dead Sea Graben - reveal contrasting thermal regimes. The coalification profile from the Hula Depression indicates a relatively high thermal gradient, averaging 40°C/km, throughout the Late Cenozoic. Similarly, a relatively high heat flow, approx. 1.77 HFU, was reported in the Sea of Galilee, 35 km to the south. Coalification profile, heat flow data and BHT measurements on the Dead Sea Graben (200 km to the south) reveal a considerably lower thermal regime (approx. 0.7 HFU, 20°C/km) that has prevailed since the mid-Miocene. However, the differences in the thermal regime do not represent different mechanisms of basin formation. With the corroboration of hydrological and geophysical data, it is suggested that the high thermal regime in the two northern basins reflects a regional phenomenon associated with the nearby extensive Golan-Jebel Druze young volcanic terrain. Therefore, it has no relationship to the mechanism of rhomb-shaped graben formation, and should not be cited in support of kinematic models requiring a high thermal regime. (Author abstract)

Bein, Amos (Geological Survey of Israel, Jerusalem, Isr); Feinstein, Shimon. *J Pet Geol* v 11 n 2 Apr 1988 p 185-192.

**077481 JURASSIC FACIES IN THE LEVANT.** An attempt to display the thickness-relationship of the Jurassic facies in Israel and the immediate neighborhood, based on drilling data and outcropping Jurassic sections, is illustrated in a number of columnar sections. The Jurassic column in Northern Israel seems to counteract the Helez-Ramallah Low, and overall is thinner; the column probably belongs to a High that extends into adjacent Lebanon. The regional main depocentres indicate the wearing-down of the Arabian Massif, producing clastic, littoral and paralic sediments (e.g. the Inmar-Sherif facies) in the eastern parts of the Negev and Judea; while the influence of the Tethys Sea resulted in predominantly shallow platform carbonates (i.e. the Haifa - Lebanon facies) over most of the rest of Israel (including northern Sinai, Hermon and Lebanon). Bioherms and biostromes are most notably developed in the Brur-Nir Am facies that was initiated in the Callovian, and which as abundant stromatoporoids, but has its greatest extension in the Oxfordian. Prograding from the narrow belt of the coastal area, the Callovian is found in the NE Negev in Hamakhtesh Hagadol's Cladocoropsis-Shugraia beds. This is supposedly connected with global epeirogenic move-

ments, which in Israel are related to the 'sudden' and 'short-time' clastic Kidod deposits. The extent of the latter suggests the existence of a land-mass to the west of the present land area, concealed at great depths beneath the Mediterranean Sea. 80 Refs.

## Krasnodar Territory, USSR

**077482 BLOCK TECTONICS AND PETROLEUM POTENTIAL OF WESTERN PRE-CAUCASUS.** Deep faults identified from geological and geophysical data had a decisive influence on the history of the geological development of the territory of Western Pre-Caucasus. The basement block tectonics has been the main factor conditioning the regularities of the formation and distribution of hydrocarbon pools. An analysis of the thicknesses and litho-facies characteristics of the Paleozoic, Mesozoic and Cenozoic complexes has made it possible to evaluate the petroleum potential prospects and to recommend the arrangement of integrated geophysical explorations, and of the parametric and prospecting drilling in the indicated areas. (Translated author abstract) In Russian. 7 refs.

Lotiev, B.K.; Sazonov, I.G.; Istratov, I.V.; Kerimov, I.A. *Izv Vyssh Uchebn Zaved Neft Gaz* n 1 1987 p 9-15.

**077483 PETROLEUM AND GAS PROSPECTS OF WESTERN PRECAUCASUS IN THE LIGHT OF GEOLOGICAL AND GRAVIMETRIC DATA.** The territory of western Precaucasus is a region highly promising as regards the oil and gas potential of its deep sedimentary strata. Geological interpretation of gravitational anomalies by comparing the data of gravitational exploration, seismic exploration and deep drilling, and by establishing a relation between local gravitational anomalies and structural and tectonic peculiarities of deposits, has shown that local gravitational maxima correspond to local uplifts. Some promising local uplifts are recommended for further exploration. In Russian. 14 refs.

Kerimov, I.A. *Izv Vyssh Uchebn Zaved Neft Gaz* n 12 Dec 1987 p 9-15.

## Libya

**077484 THERMAL MATURATION HISTORY OF THE SIRTE BASIN, LIBYA.** The high degree of thermal maturity observed in shallow sediments in the western part of the Sirte Basin, Libya, requires higher geothermal gradients and/or thicker overburden in the past than exist today. The degree of thermal maturity of the Upper Cretaceous shales, the regional structure, and the subsidence history of the basin all indicate that over 3000 m of section was removed from the western flank of the basin by uplift and erosion in the mid-Tertiary. Vitrinite reflectance values in wells suggest that gradients of 1.6°F/100 ft to 1.8°F/100 ft existed in the western region at the time of peak thermal activity, in contrast with a general basin average of 1.2°F/100 ft. (Author abstract)

## Models

**077485 APPLICATION OF BOREHOLE IMAGES TO THREE-DIMENSIONAL GEOMETRIC MODELING OF EOLIAN SANDSTONE RESERVOIRS, PERMIAN ROTLIEGENDE, NORTH SEA.** High-resolution electrical borehole images of the Permian Rotliegende Sandstone (North Sea) clearly reveal a vertical succession of eolian and fluvial bedding facies. Porosities, which are found to be primarily a function of these facies, show a hierarchy of reservoir heterogeneities azimuths were measured in interdune layers, bounding surfaces, and cross-strata using, in addition to electrical images, full-circumference acoustic borehole images and dipmeter results. The vertical sequence and geometry of the bedding

elements indicate composite cross-bedding formed by downwind migration of superimposed bed forms alternating with interdune sections containing only few single bed forms. Statistical modeling of the thickness and foreset direction of cross-bedded sets is shown to constrain the three-dimensional geometry of the sand bodies. The results statistically predict distances at which wells are not connected by highly porous layers. Additional study results are discussed. (Edited author abstract). 42 Refs.

## Nebraska

**077486 WESTERN NEBRASKA: THE LATE PALEOZOIC COMES OF AGE.** Within the past several years, a new and highly successful Paleozoic oil play has emerged in the western panhandle of Nebraska. It has evoked widespread new interest in the whole of the northern Denver-Julesburg basin. The paper presents a historical perspective of the drilling activity in the area, a survey of the geotectonic history of the northern Denver basin, structural geology, descriptions of the Permo-Pennsylvanian carbonate cycles of the northern Denver-Julesburg basin and of its late Paleozoic productive intervals, as well as a brief summary of the Amazon field. The practices and problems of drilling and completion and basic exploration economics are also discussed. 79 refs.

Anon. *Pet Front* v 4 n 1 1987 74p.

## Nevada

**077487 NEVADA: THE NEXT GREAT AWAKENING? PART 1: COMPREHENDING THE COMPLEXITIES.** This is the first of a two-volume study on the petroleum geology and exploration potential of Nevada, one of the least explored of the proven frontier regions in the continental United States. The geology of Nevada is highly unique and often very complex. This issue summarizes the current state of knowledge and thinking with respect to the region. It includes an introductory overview; discussions of geotectonic history, reservoir/source rocks and structural features; a history of drilling activity; exploratory strategies; and drilling problems/solutions. A series of stratigraphic sections derived from a representative spectrum of localities (ranges) is provided in an appendix.

**077489 HIGH-TEMPERATURE DIAGENESIS IN SHALLOW CHALK RESERVOIR, SKJOLD OIL**

**FIELD, DANISH NORTH SEA: EVIDENCE FROM FLUID INCLUSIONS AND OXYGEN ISOTOPES.** Samples of calcite-filled fractures from the chalk reservoir of the Skjold oil field were studied by fluorescence microscopy, cathodoluminescence microscopy, fluid inclusion microthermometry, and oxygen and carbon stable isotope and trace element analyses. Two generations of calcite infilling are tentatively related to two major phases of faulting caused by salt movements. Results of the fluid inclusion studies suggest a precipitation temperature of the infilling calcite significantly above what it should be, applying today's geothermal gradient to the past. This higher temperature indicates that hot water ascending from deeper strata may have flushed the reservoir, apparently during a late Miocene to Pliocene faulting phase when ring faults guided the water to the reservoir. (Edited author abstract) 31 refs.

Jensenius, Jorgen (Univ of Copenhagen, Copenhagen, Den). *AAPG Bull* v 71 n 11 Nov 1987 p 1378-1386.

**077490 MOVEMENT OF HYDROCARBONS IN SHALES.** The authors have analyzed Kimmeridge Clay (Upper Jurassic) shales from the North Sea which are currently expelling hydrocarbons into adjacent sandstones. The results could be explained if most expulsion occurs by the pressure-driven flow of a discrete hydrocarbon phase through the pores of shales and into the pores of the sandstones, as suggested previously. In addition, capillary forces seem to increase the efficiency of expulsion close to the interfaces between the shales and interbedded sandstones. It appears that molecular diffusion of hydrocarbons with less than about ten carbon atoms alters the composition of the hydrocarbon fluids remaining in, and expelled from, the shales. (Edited author abstract) 10 refs.

Mackenzie, A.S. (BP Petroleum Development Ltd, London, Engl); Leythaeuser, D.; Muller, P.; Quigley, T.M.; Radke, M. *Nature* v 331 n 6151 Jan 7 1988 p 63-65.

**077491 APPLICATION OF HEAVY-MINERAL ANALYSIS TO LITHOSTRATIGRAPHY AND RESERVOIR MODELLING IN THE OSEBERG FIELD, NORTHERN NORTH SEA.** Three distinctive detrital garnet associations have been recognized in Brent Group sandstones of the Oseberg area (northern North Sea) by means of electron microprobe analysis. These have lithostratigraphical significance, with one association occurring in the Eivie and Oseberg Formations, one in the Ness Formation and one in the Tarbert Formation. Differentiation of Ness and Eivie/Oseberg Formations by means of detrital garnet geochemistry has enabled the recognition of fluvial channel sandstones belonging to the Ness Formation which have cut down into the Eivie Formation shoreline complex. This provides direct evidence of communication between Ness and Eivie/Oseberg, adding an extra degree of sophistication to the geological input for reservoir simulation. A strong permeability anisotropy can be modelled around the fluvial channels, and a net sand volume can be modelled in agreement with channel orientation. (Edited author abstract) 9 refs.

Hurst, Andrew (Statoil, Forus, Stavanger, Norw); Morton, Andrew C. *Mar Pet Geol* v 5 n 2 May 1988 p 157-169.

**077492 SEDIMENTOLOGY AND RESERVOIR POTENTIAL OF A 'MARGINAL FACIES' LIMESTONE FROM THE CRETACEOUS OF THE NORTH SEA.** The lower Cretaceous section of UK North Sea well 3/16-1, on the eastern flank of the Shetland Platform, drilled by Sovereign Oil & Gas plc, is dominated by marine 'shelf-type' limestones with a very low argillaceous content. In this respect it differs both from the typical open-sea coccolith-rich Chalk and from the argillaceous Cretaceous of the Viking Graben. Diagenesis has resulted in crystal overgrowths, corrosion, and development of very fine to coarsely crystalline void filling calcite. Hydrocarbon staining is confined to patches of void-filling calcite and partially cemented fractures. No oil staining was observed in the carbonate matrix. The lithological and petrophysical characteristics of the interval are similar to the Chalk Group of Norwegian well 1/3-1. The thickness is considerably less in 3/16-1,

probably as a result of deposition on a topographic high such as existed along the margins of the Viking Graben and the East Shetland Platform during the Cretaceous. (Edited author abstract) 31 refs.

## North Slope, Alaska

**077493 POROSITY ENHANCEMENT FROM CHERT DISSOLUTION BENEATH NEOCOMIAN UNCONFORMITY: IVISHAK FORMATION, NORTH SLOPE, ALASKA.** Secondary porosity caused by chert dissolution is common in the hydrocarbon-producing fluvial facies of the Ivishak Formation (Triassic), North Slope, Alaska. Petrographic observations suggest that macroporosity caused by chert dissolution tends to increase toward the Neocomian unconformity. In the Prudhoe Bay field, a lateral increase in core porosity (from 15 percent at about 30 km from the unconformity to 30 percent near the unconformity) and in permeability (from 50 md at about 30 km from the unconformity to 800 md near the unconformity) is evident toward the unconformity. This increase occurs within the fluvial facies (zone 4) of nearly uniform grain size and framework composition (chert litharenite). Major chert dissolution probably took place during the Neocomian uplift when the Ivishak Formation was exposed to acidic meteoric waters in the near-surface environment. (Author abstract) 39 Refs.

## Norway

**077494 ENVIRONMENTAL SETTING AND DIAGENESIS OF LOWER PERMIAN PALAEOPLYSINID BUILD-UPS AND ASSOCIATED SEDIMENTS FROM BJORNOYA: IMPLICATIONS FOR THE EXPLORATION OF THE BARENTS SEA.** Lower Permian palaeoptysinid build-ups, interbedded with inter-build-up lagoonal sediments, occur both on Bjornoya and in the subsurface of the Barents Sea. They formed on a low-energy, broad and shallow shelf, and show a cyclic development which was probably related to minor eustatic sea-level changes. During periodic lowering of sea level, build-ups were subaerially exposed, meteoric diagenesis with karstification took place within the build-ups, and hypersaline conditions prevailed in the lagoons. In the Barents Sea, the palaeoptysinid build-ups have composite thicknesses on the order of several hundred metres and are restricted to positive structural elements. They are regarded as potential reservoir rocks in this area, partly because of the high porosity of similar build-ups in Central Spitsbergen. The reservoir quality of the build-ups on Bjornoya and from the single cored build-up complex in the Barents Sea is, however, relatively poor. Early Tertiary fracturing increased the permeability of the bulk rock, but also caused leakage of accumulated hydrocarbons. (Edited author abstract)

## Reviews

**077495 HYDROCARBON POTENTIAL AND TECTONICS OF INDOCHINA.** The region under discussion is that part of Indochina which includes Vietnam, Laos, Kampuchea and eastern Thailand. The Kontum Massif, composed of a metamorphosed basement complex, is the core of the Indochina region, and crops out from eastern Vietnam to Laos and Kampuchea. The concept of concentric growth of orogenic belts along the periphery of this massif seems to have been accepted as being within the scope of the classic theory of orogeny. The application of a modern plate-tectonic hypothesis with the aid of Landsat image analysis, has, however, enabled a new interpretation of the tectonic development of the area to be made. The hydrocarbon potential of Indochina is here investigated, based on this interpretation of the region's tectonic development, and taking account of the morpho-

logical and textural characteristics detected from Landsat imagery. Three areas: (1) the Mekong Delta, (2) the Khorat Plateau, and (3) the Hanoi Basin-Gulf of Tonkin, are selected for detailed discussion of their hydrocarbon potential. (Author abstract)

**077496 MIDDLE BEDS LOG-CORE CORRELATIONS IN TATAGWA OIL FIELD, SOUTHERN SASKATCHEWAN, CANADA.** The present study provides a review of the lithology, corresponding core data and down-hole log parameters from the Tatagwa oil field. It includes a brief description of the lithologic types which can be recognized as the 'Marly' and 'Vuggy' units, a petrological study based on thin section. X-ray diffraction and scanning electron microscopy, and a summary of standard core and down-hole log data. The benefits derived from a correlation between the core data and the log parameter are threefold: more realistic down-hole log charts, better volumetric estimates of reserves, and an accurate data base for enhanced recovery. It is shown that the use of down-hole logs in combination with coring through the prospective zones is essential for the proper evaluation of this type of reservoir. (Author abstract) 8 refs.

## Sedimentology

**077497 THE muPETROL EXPERT SYSTEM FOR CLASSIFYING WORLD SEDIMENTARY BASINS.** muPETROL, an operational prototype expert system, patterned after muPROSPECTOR, provides the means for classifying sedimentary basins of the world as a first step in developing an integrated expert systems approach to estimating undiscovered worldwide petroleum resources. The basin classification is based on nine sedimentary basin models using H.D. Klemme's recognition criteria for a world sedimentary basin classification system. Each model is defined by a rule-based system and embodies the geologic concepts of plate tectonics modified by regional tectonics and lithologic and depositional sequences. The system of rule-based models is used to evaluate the likelihood of one hydrocarbon occurrence or more in a basin on the basis of the geologic characteristics that categorize that basin. These characteristics are also matched against those of known basins in a data base containing nearly 800 world basins. (Edited author abstract) 59 refs.

**077498 RELATIONSHIPS BETWEEN THERMAL MATURITY INDICES CALCULATED USING ARRHENIUS EQUATION AND LOPATIN METHOD: IMPLICATIONS FOR PETROLEUM EXPLORATION.** Thermal maturity can be calculated with time-temperature indices (TTI) based on the Arrhenius equation using kinetics applicable to a range of Types II and III kerogens. These TTIs are compared with TTI calculations based on the N.V. Lopatin method and are related theoretically (and empirically via vitrinite reflectance) to the petroleum-generation window. Heating rates control the thermal-maturation trends of buried sediments. Relative to Arrhenius TTIs, Lopatin TTIs tend to underestimate thermal maturity at high heating rates and overestimate it as low heating rates. Complex burial histories applicable to a range of tectonic environments illustrate the different exploration decisions that might be

made on the basis of independent results of these two thermal-maturation models. (Edited author abstract) 46 refs.

**077499 SEDIMENTOLOGY AND CHARACTERISTICS OF DISPERSED ORGANIC MATTER IN TERTIARY NIGER DELTA: ORIGIN OF SOURCE ROCKS IN A DELTAIC ENVIRONMENT.** The distribution and abundance of the organic matter are related to both the age of the strata and depositional environment. The most significant variation is the decline in mean total organic carbon (TOC) content from late Eocene (2.2% TOC) to Pliocene strata (0.9% TOC) and an associated general decline in pyrolysis-defined hydrogen index (HI) and pristane/phytane ratio. The decrease in TOC and HI in younger strata reflects increased dilution of a nearly constant supply of terrestrial organic matter with the generally higher sedimentation rates of younger strata. The variation in organic matter with depositional environments and environmental depth zones (defined by foraminiferal assemblages) is significant, although less important than variation due to age. Paradoxically, no rich source rocks occur in the Tertiary succession in the Niger delta and, as conventionally measured, the strata have little or no oil-generating potential. Additional aspects of the subject are discussed. (Edited author abstract) 55 refs.

**077500 DEEP-WATER DENSITY CURRENT DEPOSITS OF DELAWARE MOUNTAIN GROUP (PERMIAN), DELAWARE BASIN, TEXAS AND NEW MEXICO.** The Guadalupian Delaware Mountain Group is a 1,000-1,600-m thick section of siltstone and sandstone deposited in a deep-water density-stratified basin surrounded by carbonate banks or reefs and broad shallow evaporite-clastic shelves. The most prevalent style of basinal deposition was suspension settling of silt. Channels can be observed in outcrop at the basin margin and can be inferred from closely spaced wells in the basin. Hydrocarbon sealing beds are provided by laminated organic siltstone, which laterally can form the erosional margin where channels are cut into siltstone beds. Thick beds of very fine-grained sandstones fill the channels. These sandstones contain abundant large and small-scale traction-current-produced stratification. Outcrop and subsurface evidence indicates Delaware Mountain Group sediments were deposited by saline density currents. Exploration predictions based on submarine fan models formed by turbidity currents would anticipate very different proximal-distal changes in sandstone geometry and facies. Additional aspects of the subject are discussed. (Edited author abstract) 55 refs.

**077501 ZOOPLANKTON FECAL PELLETS AS A SOURCE OF HYDROCARBONS IN CHALK.** Evidence from biochemistry, marine geology and sedimentology shows that chalk could be a source of hydrocarbons, and that some hydrocarbons in some chalk reservoirs could have originated within the chalk. Coccolith ooze, the precursor of chalk is deposited as the fecal pellets of zooplankton, most probably copepods. These fecal pellets contain dihydrophytol, which is a precursor of pristane; the latter is a precursor of some crude oil deposits. Zooplankton fecal pellets probably provided the organic source for some of the hydrocarbons in chalk. Some hydrocarbons in marine- and lacustrine-shale source rocks could have originated in much the same way. (Edited author abstract) 32 Refs.

## Somalia

**077502 FOLDING OF THE MESOZOIC COVER IN SW SOMALIA: A COMPRESSIONAL EPISODE RELATED TO THE EARLY STAGES OF INDIAN OCEAN EVOLUTION.** The tectonic-sedimentary evolution of SW and central Somalia is characterized by two main depositional cycles. The first cycle (Triassic to Early Cretaceous) is characterized by subsiding basins related to a process of crustal thinning, and is associated with the separation of Madagascar from Africa, between 165 and 121 million years ago. The second cycle, starting in the Late Cretaceous with a regional unconformity, is related to the separation and northeastward drift of India, at approximately 80 million years ago. The folds that affect the Jurassic and Early Cretaceous formations of the Lugh-Mandera basin in SW Somalia are the result of a compressive phase connected with dextral transcurrent movements along NE-SW trending fracture zones. These zones are developed parallel to the oceanic system of transform faults, in connection with the change in the stress regime intervening at the shift of the direction of spreading between the first and the second stages of evolution of the Indian Ocean. (Edited author abstract)

**077503 'ALBIAN TRANSGRESSION' IN THE SOUTHERN NORTH SEA BASIN.** The 'Albian transgression' may be recognized lithostratigraphically in a number of boreholes in the UK sector of the southern North Sea Basin. This event is also recognized onshore the United Kingdom. The importance of this event for hydrocarbon exploration is discussed, and comparisons are made with sections in West Germany. The 'Albian transgression' is a regional event in NW Europe which is important for understanding the pattern of basin evolution during Early and 'Mid' Cretaceous times. It is also important because the diachronous coarse clastics associated with the transgression may prove to be of important reservoir potential in the southern North Sea area (UK sector). (Author abstract) Refs.

Crittenden, Stephen (Gearhart Geo Consultants Ltd, Aberdeen, Scotl). *J Pet Geol* v 10 n 4 Oct 1987 p 395-414.

**077504 STRATIFICATION OF THE SEDIMENTARY COVER AND DETERMINATION OF THE NATURE OF DISCREPANCIES WITHIN THE PRE-CASPIAN LOWLAND ON THE BASIS OF A SEISMOSTRATIGRAPHIC ANALYSIS.** Results of the first-time application of the principles of seismostratigraphy to a number of petroliferous fields of the Precaspian lowland are presented. This method was used to describe the wave picture on temporal logs with the purpose of identifying the Cenozoic complex strata as sedimentary series and establishing more precisely the nature of the breaks and discrepancies in the sedimentary cover. **077505 STRATIGRAPHY, RESERVOIR CHARACTERISTICS OF BEREASANDSTONE IN MICHIGAN FIELDS.** This report concerns the stratigraphy and reservoir characteristics of the Berea sandstone in the Larkin and Williams fields of Midland and Bay counties of Michigan. A cross section was constructed across the Larkin through Williams area using computerized gamma ray logs.

Gunn, George R. (Sun Exploration & Production Co, Dallas, TX, USA). *Oil Gas J* v 86 n 10 Mar 7 1988 p 57-60.

**077506 RESERVOIR CHARACTERISTICS OF THE KEWEENAWAN SUPERGROUP, LAKE SUPERIOR REGION.** This is a brief review of the stratigraphic, sedimentologic, and petrographic characteristics of the several thousand meter thick, post-volcanic siliciclastic Keweenaw Supergroup in the Lake Superior region with an emphasis on petroleum reservoir potential. During late Precambrian time, many sedimentary and volcanic rock units were deposited in the Lake Superior region. The upper Precambrian rock column can be thought of as consisting of three sequences: pre-volcanic quartz sandstone, Keweenaw volcanic rock, and the post-volcanic sedimentary rock units that are the subject of this paper. Keweenaw Supergroup rock, a red bed sequence that includes the Oronto Group and the overlying Bayfield Group, and their correlative rock units, are dominated by coarse clastic units that have potential as reservoir rock for petroleum that may have been generated within the Nonesuch Shale during deep burial.

Ojakangas, Richard W. *Geosci Wis* v 11 Sept 1986 p 25-31.

**077507 SOURCE ROCK EVALUATION OF HEATH FORMATION (MISSISSIPPIAN) IN MONTANA THRUST BELT.** The Heath formation of the Big Snowy group (Mississippian) consists of dark-gray to black, petroliferous shale and limestone that were deposited in an east-trending marine trough that extends from West Central Montana to western North Dakota. The authors' work in the overthrust belt of West Central Montana indicates that maturation of rocks of the Heath formation there proceeded beyond the preservation limits of oil and wet gas, and probably dry gas. Therefore, the Heath passed through peak hydrocarbon generation zones and the hydrocarbons may have been thermally destroyed. Modeling of the depositional and thermal history of this part of the Montana overthrust belt using the Lopatin method indicates the prior-to-thrusting maturation was slightly below the oil generation window. They interpret hydrocarbon generation to have occurred after thrusting, probably in response to tectonic burial beneath thrust sheets with dry gas the only hydrocarbon possible present.

**077508 CEMENT STRATIGRAPHY OF PENNSYLVANIA HOLDER FORMATION, SACRAMENTO MOUNTAINS, NEW MEXICO.** Cyclic strata of the Holder Formation (Virgilian, New Mexico) were deposited across a Pennsylvanian shelf-to-basin transition during a time when sea level fluctuated over tens of meters. Cement-stratigraphy studies indicate abundant calcite precipitation from low-temperature fresh water within shelf, shelf-crest, and shelf-edge marine limestones. Fresh-water cementation occurred during 15 periods of intraformational subaerial exposure. Distribution of early calcite cements provides new data for interpretation of cycles, diagenetic systems, and porosity evolution in petroleum reservoirs. Trace-element analyses support a low-temperature, freshwater origin for the early cements. Cement-stratigraphy studies, fluid-inclusion analyses, and trace-element analyses indicate a later cement that occluded remaining limestone porosity precipitated from a sodium- and calcium-rich brine at a temperature of about 100°C. Additional study results are discussed. (Edited author abstract) 56 Refs.

## Sultanate of Oman

**077509 STRATIGRAPHY AND ROCK UNIT NOMENCLATURE IN THE OIL-PRODUCING AREA OF INTERIOR OMAN.** The sedimentary rock sequence in the oilfield areas of Interior Oman ranges from the Late Proterozoic through Paleozoic, Mesozoic and Tertiary. A number of major gaps or changes in sedimentation are

recognized, and these punctuate a subdivision into major rock units ranked as groups. Eleven named groups are recognized. Most of these groups are further subdivided and 35 named formations are described giving lithologic characteristics, boundaries, inferred age span and variability. These descriptions, together with reference well sections indicating wire-line log characteristics, provide a sufficient basis for consistent future use of the rock units. Hydrocarbon occurrence within this sedimentary sequence is primarily controlled by the presence of good impermeable sealing units, particularly those of sufficient thickness to be least breached by faulting. Seven important sealing units are recognized. Commercial hydrocarbon accumulations are retained by all these seals. Reservoirs are in both carbonate and clastic units, and in South Oman are commonly in much older units than the seal, which overlies unconformably. (Edited author abstract) Refs.

Hughes Clarke, Michael W. (Petroleum Development Oman LLC, Muscat, Oman). *J Pet Geol* v 11 n 1 Jan 1988 p 5-60.

**077510 ORIGIN OF CRUDE OILS IN OMAN.** The crude oils of Oman can be geochemically classified into five groups. Three groups can be related to good oil source rocks found in the pre-Cambrian Huqf Group, the Silurian Safiq and the Cretaceous Natih Formations. Another group of oils probably originates from the Upper Jurassic Diyab Formation, while the fifth group of crudes (named 'Q') cannot be correlated to a known source rock, but is inferred to have originated from an unsampled Huqf level. The 'Huqf oils' are those that have been correlated to known Infra-Cambrian Huqf source rocks, and are characterized by a strong  $C_{29}$  sterane predominance and very light carbon isotope values of around  $-36.0/0.00$ . In contrast, the 'Q' crudes, derived from the unknown source, are characterized by a  $C_{27}$  sterane predominance and carbon isotope ratios of around  $-30.5/0.00$ . Oils reasoned to originate from Silurian Safiq source rocks have a weak  $C_{29}$  sterane predominance, a significant content of rearranged steranes and carbon isotope ratios of  $-30.5/0.00$ . The oils thought to originate from the Jurassic Diyab Formation have a similar sterane distribution but heavier carbon isotope values of around  $-26.5/0.00$ . Finally, the crude oils from the mid-Cretaceous Natih Formation source rocks are characterized by steranes with an equivalent distribution of  $C_{27}$ ,  $C_{28}$  and  $C_{29}$  isomers, and carbon isotope values of around  $-26.9/0.00$ . (Edited author abstract) Refs.

**077511 EVIDENCE OF PERMO-CARBONIFEROUS GLACIATION IN THE BASAL MURBAT SANDSTONE FORMATION, SOUTHERN REGION, SULTANATE OF OMAN.** The most massive basal diamictite of the Murbat Sandstone Formation exhibits many sedimentary features which indicate its subglacial deposition. Some of the most important features are: (1) striated and grooved sandstone slivers within the diamictite; (2) striated and faceted clasts; (3) small stratified sandstone lenses within the diamictite; (4) 'dropstones' or 'out-of-size clasts' in the shale; and (5) the large lateral and vertical extent of the diamictite. The overlying sequence of the Murbat Sandstone Formation consists of an alternating succession of conglomerate and sandstone followed by siltstone and shale, whose sedimentary structures, however, suggest their deposition in deeper-water basins. The Murbat Sandstone Formation has been assigned to various ages ranging from Infra-Cambrian to Ordovician by different workers, in view of its isolated occurrence and the absence of flora and fauna. The Metal Mining Agency of Japan, however, has dated the Murbat Sandstone Formation as Permo-Carboniferous, as it unconformably overlies Lower Carboniferous dikes of the crystalline basement. The dikes have been dated by the K-Ar method. 13 refs.

## Tanzania

**077512 GAS-PRONE SOURCE ROCKS FROM CRATOGENE KAROO BASINS IN TANZANIA.** Source-rock quality and organic matter maturity of coals and sediments from several Tanzanian Karoo basins (Permian-Triassic) have been evaluated by microscopic, pyrolytic and geochemical methods. The intracratonic Ruhuhu Basin (SW Tanzania) differs from two peripheral cratogene basins (Mikumi and Rufiji) with respect to the composition of organic matter, thermal evolution and probable hydrocarbon generation in a tensional tectonic stress field of the East African craton at the Palaeozoic/Mesozoic boundary. The Lower Permian sediments and coals and the Upper Permian sediments of the Ruhuhu Basin exhibit moderate source-rock properties. They were not subjected to significant subsidence and are moderately mature source rocks. They possibly experienced temperatures in the range  $60-110^{\circ}\text{C}$  and vitrinite reflectance values of  $0.5-0.8$  were attained, thus placing them within the 'oil window'. Kerogen Type III is typical for all the basins, and productivity indices indicate moderate to advanced stages of evolution. The coastal basins differ in most parameters. The sediments do not have source-rock properties. High vitrinite reflectance values ( $1.0-2.0\%$ ) imply a higher degree of thermal maturation, and geochemical results confirm that organic matter in these sediments is postmature, and that hydrocarbon generation, if it occurred at all, ceased some time ago. (Edited author abstract)

**077513 FAULT SLICING - A NEW APPROACH TO THE INTERPRETATION OF FAULT DETAIL.** The manner in which a fault intersects a hydrocarbon reservoir affects production characteristics and thus must be understood in great detail. A 3-D seismic data volume can be sliced interactively to yield seismic sections parallel to a fault plane. These fault slices can then be used in several ways for the study of faults. Tracking of correlative horizons on fault slices provides a map of fault throw and permits study of the throw as a function of vertical traveltime and horizontal position. Because a fault slice remains within one major fault block, the study of growth relationships in that block is facilitated. Splinter faults, which are also significant in development and production, can be studied effectively on fault slices because of the uniform proximity of these sections to the parent fault. (Edited author abstract)

Brown, Alistair R. (Geophysical Service Inc, Dallas, TX, USA); Edwards, G. Serpell; Howard, Robert E. *Geophysics* v 52 n 10 Oct 1987 p 1319-1327.

**077514 TECTONIC BASIS FOR SEPARATE FORECASTING OF OIL AND GAS POTENTIAL OF SEDIMENTARY ROCK BASINS OF PLATFORMS AND FOREDEEPS.** Based on the data on the Azov-Kuban, Middle Caspian West Siberian and other oil and gas-bearing basins ( $>50$  deposits), a new historical-dynamic method of predicting oil and gas potential has been developed. It consists in the utilization of a set of structural and paleotectonic indices - static (morphology, size, time of formation of folds) and dynamic (rate and gradients of sedimentation, rate of growth of local uplifts, contrasts). The basis of the method is identification of terrigenous, terrigeno-carbonate and carbonate formations of a normally marine type of compensated sedimentation. In Russian.

D'yakov, A.I.; Geiro, S.S.; Rodygin, V.R. *Geol Nefti Gaza* n 2 1987 p 32-34.

**077515 CONTINENTAL CRUST UNDER THE NW PACIFIC OCEAN.** Reinterpretation of seismic profiles and DSDP drilling results, together with dredging data from the Japan Trench and Nankai Trough areas, NW Pacific, shows that the so-called oceanic crust is composed of Precambrian continental crust, consisting partly of Proterozoic orthoquartzite. This is supported by paleogeographic evidence, which requires the presence of large continental masses on the present Pacific side of the Japanese islands during Paleozoic-Mesozoic-Paleogene times, as source areas for the large volume of sediments carried into the Japanese part of the Tethys. Most of the present NW Pacific was either subaerially exposed or was partly very shallow sea during Paleozoic to Early Mesozoic times, and first became deep sea about the end of the Jurassic. These conclusions require the fundamental revision of plate-tectonic models for the geological development of the island arcs and trenches in the NW Pacific region. (Author abstract) Refs.

Choi, D.R. *J Pet Geol* v 10 n 4 Oct 1987 p 425-440.

**077516 MAIN PROBLEMS OF TECTONODYNAMICS AND OIL AND GAS ONTOGENESIS.** An attempt is made to show the potentialities and the main problems of tectonodynamic evaluation of the conditions of formation of oil and gas pools. This approach is termed tectonodynamics of the ontogenesis of oil and gas, meaning the area of studies of a complex of natural processes that are a function of the nonlinear-variable dynamic effects of a tectonic nature that exerts an influence on the direction and style of oil and gas formation and accumulation. In Russian. 12 refs.

Amurskii, G.I.; Solov'ev, N.N. *Geol Nefti Gaza* n 4 Apr 1987 p 34-39.

**077517 MIDCONTINENT RIFT AS A FRONTIER HYDROCARBON TARGET.** Graben development by crustal extension approximately 1.1 Ga, followed by infilling by numerous basaltic flows, and isostatic sinking of volcanic rock created erosion and deposition of older (Oronto Group) sedimentary rock with reactivation and uplift of the central (St. Croix) horst. The Oronto Group was eroded and the sediment deposited as Bayfield Group sedimentary rock in the flanking basins; erosion of St. Croix Horst continued into Paleozoic time until terminated by transgression of Lower Paleozoic units. The basic structure of the Midcontinent Rift System southwest of Lake Superior is a central horst block flanked by basins. The trend of the central St. Croix Horst is not continuous. In Wisconsin the Oronto Group is associated with the Ashland-Lake Superior Syncline. To the southwest a 580 m column of Oronto-like sedimentary rock was drilled south of Minneapolis-St. Paul in search of suitable natural gas storage reservoir.

Dickas, Albert B. *Geosci Wis* v 11 Sept 1986 p 15-19.

**077518 LITHOSPHERIC FLEXURE AND EVOLUTION OF THE MIDCONTINENT RIFT.** Seismic reflection and refraction data give two snapshots of basin evolution. The following scenario is suggested for the evolution of the Midcontinent Rift System in this region: extension and high heat flow thins the lithosphere, and the mantle material intrudes the lower crust; volcanic activity ceases and the cooling intrusion contracts, increasing in density and loading the crust; sedimentation keeps pace with the deepening basin; and subsidence stops when the intrusive body has cooled. The St. Croix Horst is thrust up along the Douglas and Lake Owen Faults. The intracrustal body is preserved by the stable cratonic environment, but as the lithosphere thickens compensation occurs at a greater depth and with a longer wavelength reflected in the present day deformation of the Moho.

Nyquist, Jonathan E.; Wang, Herbert F. *Geosci Wis* v 11 Sept 1986 p 19-21.

**077519 SOME DEFORMATION EFFECTS IN A CLASTIC OVERBURDEN RESULTING FROM SALT MOBILITY.** In a basin containing an evaporite sequence that includes salt rock, should the salt become mobile and deform plastically, it will produce important structural effects in overlying sediments. These effects may include folding, faulting, slumping, and in some cases where dissolution of the salt also occurs, collapse structures. The movement of the salt/overburden system during plastic deformation of the salt may be syndepositional, in which case rim syncline sedimentation will take place at the surface. The form taken by the rim syncline deposits will be related to the stage of development of the salt structures with which they are associated. An understanding of the mechanisms involved is important, particularly in a basin containing hydrocarbons. Also, study of the behavior at depth of sediments which are subject to deformational stress may assist in solving structural problems on the larger, regional scale. Selected examples of various effects seen in the North Sea Zechstein salt basin are discussed and illustrated with recently acquired seismic data. (Author abstract). 17 Refs.

Texas

**077520 COMPOSITE CLASSIFICATION OF FRACTURED AND BRECCIATED CARBONATE ROCKS - EXAMPLES FROM THE ORDOVICIAN ELLENBURGER GROUP, WEST TEXAS.** The attention paid to rock fracturing in recent years is a result of the discovery of large volumes of hydrocarbons in fractured rock reservoirs. This regional study was conducted in order to facilitate a better understanding of the performance of fractured reservoirs, and to select the proper procedures and well intervals for artificial fracturing. Five classification schemes are proposed for fracture, breccia, porosity and permeability developments, as revealed by mega- and microscopic examination of cores, thin-sections and outcrop samples. A composite classification combines the attributes of the other schemes in an attempt to predict residual porosity and permeability on a reservoir scale. Various genetic types of breccia were encountered in this study, but those of tectonic origin predominate and control hydrocarbon production. (Edited author abstract)

Thailand

**077521 STRUCTURAL CONTROL OF NEOGENE SEDIMENTATION IN THE MAE SOT BASIN (THAI-BURMESE BORDER): IMPLICATIONS FOR OIL-SHALE RESERVES.** The Mae Sot Basin is here interpreted as a tilted fault-block bounded on the east by a normal fault which, acting as a growth fault, controlled sedimentation during the Neogene. It is suggested that oil-shale reserves are greater than those currently estimated, and that they may be greatest near the eastern margin of the basin due to the development of a thicker sequence here, and repetition of the facies at depth in sedimentary cyclothem. (Author abstract). 17 Refs.

Stokes, R.B. (Kingston Polytechnic, Kingston upon Thames, Engl). *J Pet Geol* v 11 n 3 Jul 1988 p 341-346.

Theory

**077522 GEOLOGICAL REASONING FOR THE PETROLEUM SOURCE ROCKS OF KNOWN FIELDS.** Geological reasoning for the petroleum source-migration-accumulation relationships centres around petroleum composition and its variability, water composition and its variability, and stratigraphy. The author argues hypothesis of petroleum origin and migration mechanism will be satisfactory unless all observations, geological, hydrogeological, and geochemical, can be reconciled; and no hypothesis can be satisfactory that does not take geological argument into account. The purpose of this paper is to examine geological arguments

for the location of petroleum source rocks, and to discuss some fields where the published geochemical conclusions appear to be contradicted by the geological evidence. 40 refs.

Thermal Effects

**077523 INVERSION OF BOTTOM-HOLE TEMPERATURE DATA: THE PINEVIEW FIELD, UTAH-WYOMING THRUST BELT.** The present-day temperature field in a sedimentary basin is a constraint on the maturation of hydrocarbons; this temperature field may be estimated by inverting corrected bottom-hole temperature (BHT) data. Thirty-two BHTs from the Pineview oil field are corrected for drilling disturbances by a Horner plot and inverted for the geothermal gradient in nine formations. Both least-squares ( $l_2$ ) norm and uniform ( $l_1$ ) norm inversions are used; the  $l_1$  norm is found to be more robust for the Pineview data. The inversion removes random error from the corrected BHT data by partitioning scatter between noise associated with the BHT measurement and correction processes and local variations in the geothermal gradient. (Edited author abstract) 33 refs.

Turkmen SSR

**077524 KUMBET-KARADZHAULAK UPLIFT ZONE - A NEW PROMISING REGION FOR HYDROCARBON RESOURCE EXPLORATION IN TURKMENIA.** The Kumbet-Karadzhaulak uplift zone and the gas-condensate deposits associated with it have been discovered in the above-salt Titon-Valanzhian level of the outer fringe of the Pre-Kopetdag border trough. Further prospects of the gas and oil potential of the zone are connected with the subsalt Carbonate level of the Oxfordian Aier, as well as with the continuation of the exploration of the above-salt level. Lithological-type pools may be discovered there. A program of drilling work is suggested. (Edited author abstract) In Russian.

Ulyanov Region, USSR

**077525 NEW DATA ON THE OIL BEARING CAPACITY OF THE PALEOZOIC OF THE TRANS-VOLGA PART OF THE ULYANOV REGION.** The oil-bearing capacity of the Devonian strata has been established as a result of drilling at the Labitovskoe uplift (at the south-eastern fringe of the Ulyanov region). This encourages the search for similar deposits in the same formations in neighboring areas, in particular within the confines of the Melekess trough which has not been adequately explored yet. In Russian. 4 refs.

**077526 ORIGIN AND RECOGNITION OF LATERALLY CONTINUOUS CARBONATE-CEMENTED HORIZONS IN THE UPPER LIAS SANDS OF SOUTHERN ENGLAND.** The Upper Lias Sands of southern England contain numerous, laterally extensive, carbonate-cemented horizons. Petrographical analyses of samples from outcrop sections and the Marchwood No. 1 borehole indicate that these horizons result from preferential cementation of bioclast-rich, clay-poor sediments by

comparison with interbedded clay-rich, bioclast-poor sediments. The alternation of the two sediment types is attributed to the effects of, respectively, fairweather and storm processes on a submerged marine shoal. Petrographical and ichnological data indicate an early distinction of the strongly and weakly cemented horizons. The widespread extent of the cemented horizons, as indicated by outcrop studies on the Dorset coast, is considered to be a direct consequence of episodic storm activity on the low relief shoal. Sedimentological, palynological and petrophysical criteria are presented to assist in recognition of similar extensive cements in subsurface reservoir horizons that do not outcrop. (Author abstract) 65 refs.

**077527 EARLY CARBONIFEROUS OF THE SOLWAY BASIN: A TECTONOSTRATIGRAPHIC MODEL AND ITS BEARING ON HYDROCARBON POTENTIAL.** The Solway Basin forms the western portion of the Northumberland Trough, a Carboniferous basin system trending WSW-ENE across northern England. A study of the tectono-stratigraphic variations along the margins allows certain predictions to be made regarding the hydrocarbon prospectivity of the Dinantian. It is proposed that earliest Carboniferous extension initiated a series of half-grabens separated by transfer zones that have subsequently formed fold culminations and fault belts within the basin. A model for the proposed graben polarity-switching in the basin system is outlined. Differential subsidence across active faults led to pronounced facies variations in the Courcayan-Chadian which subsequently declined in importance until, in Brigantian-Pendleian times, deposition was governed by regional subsidence. The model anticipates that the best development of reservoir facies is in the distal nearshore equivalent of the Early Dinantian alluvial coarse clastics. Additional aspects of the subject are discussed. (Edited author abstract). 35 Refs.

United States

**077528 EFFECTS OF DEFORMATION MECHANISMS ON RESERVOIR POTENTIAL IN CENTRAL APPALACHIAN OVERTHRUST BELT.** Finite strain associated with various deformation mechanisms can significantly alter the porosity and permeability of reservoir rocks in overthrust belts. Mechanisms such as pressure solution and cataclasis reduce porosity and permeability, whereas extension fracturing and brecciation increase them. It is concluded that the potential for oil production is primarily restricted to the Appalachian Plateau province. The potential for gas production decreases from west to east in the Valley and Ridge and Plateau provinces, with its approximate eastern limit defined by the North Mountain thrust. (Edited author abstract). 31 Refs.

Mitra, Shankar (ARCO Oil & Gas Co, Plano, TX, USA). *AAPG Bull* v 72 n 5 May 1988 p 536-554.

**077529 FRAMEWORK OF HYDROCARBON GENERATION AND DESTRUCTION IN EASTERN SMACKOVER TREND.** Laminated lime mudstones of the lower member of the Jurassic Smackover Formation are significant source rocks for crude oil across Mississippi, Alabama, and Florida. The source facies was deposited in an anoxic and perhaps hypersaline environment that preserved algal-derived kerogen. The distribution of kerogen along laminations of depositional origin and long stylolites of diagenetic origin resulted in efficient expulsion of crude oil. With increasing thermal maturity, crude oil initially emplaced in reservoirs was cracked to yield gas condensate and then methane rich in nonhydrocarbon gases such as hydrogen sulfide, carbon dioxide, and nitrogen. Early destruction of methane was driven by

thermochemical sulfate reduction. The thermal maturity framework of the Smackover trend explains the distribution of hydrocarbon discoveries and suggests areas previously overlooked by exploration. (Author abstract). 52 Refs.

**077530 STARYI OSKOL-PASHIAN NONCOMPENSATED TROUGHS - NEW RESERVE FOR OIL AND GAS PROSPECTING.** Noncompensated troughs (NCT) of the Upper Devonian-Lower Carboniferous age are the most promising regional targets of prospecting for oil and gas at the present time. Over 300 oil and gas deposits have been explored in these formations within the Volga-Urals oil and gas province. Promising areas are found in the Timan-Pechora province. An analysis of the Staryi Oskol-Pashian complex in the southern part of the Orenburg and Kuibyshev regions has allowed identification of the Lebyazhinskoe system of NCTs. Recommendations are given on prospecting targets in this area. In Russian. 4 refs.

**077531 CONDITIONS OF TECTONIC EVOLUTION AND PETROLEUM POTENTIAL.** Using the example of the extensive Pripyat-North-Caspian lineament, the tectonic conditions and their effects on the sedimentation and hydrocarbon pool generation are investigated. It is shown what tectonic conditions are the most favorable for the development and preservation of hydrocarbon deposits subjected to high pressures and temperatures. The Pripyat-North-Caspian lineament represents a complex structure which started, to be formed in the Riphean period. Following the accumulation of thick sedimentation strata in the Paleozoic Era, great inversions and formation of folded Herzinide structures led to the localization of hydrocarbon deposits in a zone under the overthrust. West of the Donbas, the petroliferous strata belong to the Paleozoic and east of the Donbas to the Mesozoic. In Russian. 1 ref.

#### Utah

**077532 STRUCTURAL ANALYSIS USING THRUST-FAULT HANGING-W SEQUENCE DIAGRAMS: OGDEN DUPLEX, WASATCH RANGE, UTAH.** Detailed mapping and cross-section traverses provide the control of structural analysis and geometric modeling of the Ogden duplex, a complex thrust system exposed in the Wasatch Mountains, east of Ogden, Utah. The structures consist of east-dipping folded thrust faults, basement-cored horses, lateral ramps and folds, and tear faults. The sequence of thrusting is determined by means of lateral overlap of horses, thrust-splay relationships, and a top-to-bottom piggyback development. This exposed duplex serves as a good model to illustrate the method of constructing a hanging-wall sequence diagram - a series of longitudinal cross sections that move forward in time and space, and show how a thrust system formed as it moved updip over various footwall ramps. A hanging-wall sequence diagram also shows the complex lateral variations in a thrust system and helps to locate lateral ramps, lateral folds, tear faults, and other features not shown on dip-oriented cross sections. (Edited author abstract). 31 Refs.

#### West Siberia, USSR

**077533 APPLICATION OF A COMBINATION OF SPACE PHOTOGRAPHY AND GEOPHYSICAL DATA IN STUDYING THE GEOLOGICAL STRUC-**

**TURE OF WESTERN SIBERIA.** Some results of the application of space photography data to geotectonic investigations are considered. Low effectiveness of the method of direct combined analysis of the data of aerial photography decoding and primary geophysical information for the purpose of their geological diagnostics is shown on the example of Western Siberia. An alternative method of combined interpretation of space photography, geophysical and geological data is outlined. In Russian. 6 refs.

Peskovskii, I.D.; Borovskii, V.V. *Geol Nefti Gaza* n 5 May 1987 p 7-13.

**077534 FORMATION CONDITIONS AND PETROLEUM POTENTIAL OF LOWER JURASSIC IN WEST SIBERIA.** Reground oil and gas potential of Lower Jurassic in West Siberia has been proven. Commercial hydrocarbon deposits have been detected in the western part of the Krasnoleninskii oil and gas region and to the north of it at the Bolshoye deposit in the Nyuroi depression (Nizhnetabaganskoe, Kalinovo and Urinskoe deposits), on the Nizhnevartovskii arch (Khvoinoe and Kvartovoe deposits). Noncommercial oil flows have been obtained at a number of other places. Some regularities in the location of deposits are considered and promising areas are pointed out. 3 refs. In Russian.

#### West Virginia

**077535 GEOLOGY OF DEVONIAN SHALE OIL AND GAS IN PLEASANTS, WOOD, AND RITCHIE COUNTIES, WEST VIRGINIA.** The Upper Devonian shale play of western West Virginia is an area of active development of unconventional oil and gas reserves. It is unconventional in that production is from fine-grained fractured reservoirs. Examination of recent drilling results has led to a more detailed understanding of the structure and stratigraphy of the area, which in turn can explain some of the production trends observed. Areas of greater fracture density and therefore higher productivity are related to areas of shearing motion in the Burning Springs thrust sheet. Open flows after stimulation in these wells can be very high, but first-year decline is rapid. It is uncertain at this time how long a production life these wells will have. (Author abstract) 33 refs.

#### Wisconsin See Also PETROLEUM PROSPECTING—Wisconsin.

**077536 PRECAMBRIAN PETROLEUM POTENTIAL, WISCONSIN AND MICHIGAN. I. OVERVIEW.** Nearly 700,000 acres of land have been leased for petroleum exploration in Wisconsin, and several million more acres have been leased along the Midcontinent trend in Minnesota, Iowa, and Kansas. The papers in this volume represent a summary of much of the historic information that has led to petroleum evaluation of the Midcontinent trend, and new evaluation of tectonics based on known geology and preliminary analysis of seismic data. Subjects covered include Proterozoic petroleum, and Middle Proterozoic geology of the Lake Superior area.

Mudrey, M.G. Jr. *Geosci Wis* v 11 Sept 1986 p 1-3.

**077537 EXTENT OF ORONTO GROUP.** The Nonesuch Formation of the Proterozoic Oronto Group of northern Wisconsin and Upper Michigan contains known hydrocarbon source strata. Other Oronto Group sedimentary rocks contain potential reservoir beds. Deposition of the Oronto Group was controlled by development of the Midcontinent Rift System. Within the central horst of the rift, formations are confined to the limits of the Ashland Syncline. Several areas of Precambrian sedimentation equivalent in age to the Oronto Group are known in adjacent rift-horst sections of Minnesota. (Author ab-

stract)

#### PETROLEUM INDUSTRY See Also METALS AND ALLOYS—Corrosion Resisting; OIL WELL DRILLING; PETROLEUM ENGINEERING; PETROLEUM ENGINEERING—Education; PETROLEUM REFINING; PROCESS CONTROL.

**077538 PETROLEUM ENGINEERS AND INDEPENDENT EXPLORATION AND PRODUCTION COMPANIES IN THE YEAR 2000.** This paper contains certain opinions and observations made on behalf of independent exploration and production companies regarding the future of the oil industry and of petroleum engineers. It was prepared at the request of SPE's Committee on Education and Professionalism for presentation at the 1986 SPE Annual Technical Conference and Exhibition during the depths of a serious downturn in the industry. Because our national security dictates that there must be a future for the domestic petroleum industry, the domestically oriented independent sector will be required to play a key role in that future. Petroleum and the ability to find and extract it efficiently and economically are valuable resources that will not soon nor easily be replaced. (Edited author abstract) 5 refs.

Hawkins, Warren S. (Quintana Petroleum Corp). *JPT J Pet Technol* v 39 n 10 Oct 1987 SPE 15348, p 1243-1246.

**077539 EPIDEMIOLOGICAL SURVEYS IN THE OIL INDUSTRY.** Recent epidemiological surveys in the oil industry are discussed, with particular reference to three UK petroleum related studies. These are compared with studies carried out in the USA and Canada. The UK studies comprise the retrospective mortality follow up by standardized mortality comparison with age and sex equivalent national population data over the 25 year period 1950-1975 for 34,781 employees in eight UK refineries. 23 358 employees in 700 UK bulk distribution plants and 8500 workers engaged on diesel bus maintenance. Reviewing the hypothesis testing studies shows lack of concurrence in identifying any specific excess in site specific cancer, thus arguing against the presence of any serious and consistent occupational cancer problem in refineries. (Edited author abstract) 23 refs.

**077540 EVOLUTION RECENTE DU MARCHÉ PARAPETROLIER MONDIAL.** [Recent Evolution of the World Petroleum Equipment and Service Market]. The decrease in world investments by the petroleum industry in the last four years suddenly speeded up at the beginning of 1986 with the drop in crude-oil prices. Consequently, the world petroleum equipment and service market showed a pronounced downward trend, particularly in the field of exploration and production of hydrocarbons. Geographically, this decline began in the United States before spreading to the North Sea and the rest of the world. The entire world petroleum equipment and service industry is deeply affected by this extensive degradation of the market. With such an outlook, the French petroleum equipment and service industry could have a business turnover of some 40 billion French francs and between 50,000 and 55,000 employees in 1986. (Edited author abstract) In French.

Boisserpe, P. (Inst Français du Pétrole, Rueil-Malmaison, Fr). *Rev Inst Fr Pet* v 41 n 6 Nov-Dec 1986 p 707-716.

**077541 HPI MARKETS AND STRATEGIES.** How the HPI and government react to new directions will not only set the course for the future of refining and marketing, it will have profound implications for the entire energy industry. Strategies developed by individual refiners and marketers in response to the changing environment will determine their future in the industry. Three forces have been identified and are discussed that will determine the downstream playing field in the nineties: 1. Imbalances between market demands and

refinery capacity will continue to promote intense competition and to depress margins, 2. Product and crude price volatility will be at least as great in the future as it has been in the last three years, and 3. Renewed environmental concerns will add new capital investment burdens to the industry. Why these forces have evolved and how they have led to new strategies and developments are examined.

Eklof, W.D. (Cambridge Energy Research Assoc, Cambridge, MA, USA). *Hydrocarbon Process* v 67 n 3 Mar 1988 p 125-126, 130.

**077542 VIABLE STRATEGIES FOR OIL AND GAS COMPANIES IN THE 1990S.** Key factors relating to corporate strategy formulation are discussed. The evolution of strategy at Petroleos de Venezuela is examined. The strategy of Petroleos de Venezuela is geared towards one overriding objective: to integrate our activities into the end-user market. In addition to strengthening its position in the downstream sector, the firm prefers joint ventures and to diversify its revenue base. The author indicates that the 1990s likely will be characterized by a high degree of competition in the oil industry. It is altogether probable that the buyer's market of the late 1980s will continue well into the coming decade. Regionalization will be a key word in the formulation of strategies, as sellers find it prudent to concentrate their attention on their natural markets and to service the needs of their traditional clients.

Chacin, J. (Petroleos de Venezuela, Caracas, Venez). *Hydrocarbon Process* v 67 n 5 May 1988 3p.

**077543 PROFITABILITIES ON FEDERAL OFFSHORE OIL AND GAS LEASES: A REVIEW.** This review has covered the past performance and projected future of profits from oil and gas leasing in the OCS (Outer Continental Shelf). The past performance has been dismal: a projected performance is even worse. Bonuses paid for leases are a major contributor to these unsatisfactory profits. Bonuses are also one cost that is wholly controllable by prudent management. Thus, this review arrives at its conclusion, which is that too high bonuses have been paid in the past and prudent management will pay lower bonuses in the future. 45 Refs.

Lohrenz, John. *JPT J Pet Technol* v 40 n 6 Jun 1988 p 760-764.

**077544 ASSESSING RISK IN ESTIMATING HYDRO-CARBON RESERVES AND IN EVALUATING HYDROCARBON-PRODUCING PROPERTIES.** The risks associated with estimating the reserves and value of a hydrocarbon-producing property are divided into three classifications: (1) the technical risk that the hydrocarbon values estimated by the geologists and engineers do exist in the ground and that the recoverable amounts can be recovered within the time frame projected by the engineers; (2) the economic risk that product prices, operating costs, equipment costs, inflation, and market conditions will be in reasonable agreement with the assumptions used in the economic analysis; and (3) the political risk that world economics, international political stability, taxation, and regulations will not be significantly different than projected in the evaluation. This paper focuses on these risk categories and presents methods for implementing risk estimates in the evaluation of a producing property, taking into account the maturity of the technical data, the location, and the life of the property. (Edited author abstract). 29 Refs.

## Alaska

**077546 ENVIRONMENTAL AND PETROLEUM RESOURCE CONFLICTS: A SIMULATION MODEL TO DETERMINE THE BENEFITS OF PETROLEUM PRODUCTION IN THE ARCTIC NATIONAL WILDLIFE REFUGE, ALASKA.** The Arctic National Wildlife Refuge (ANWR), located on the Alaska North Slope, is believed to contain high petroleum production potential. This region also has outstanding wildlife and wilderness values. Congress is considering an Interior Department recommendation to open a portion of ANWR to oil and gas production. A draft study by the Interior Department reports values that are used to generate an expected present value of the net economic benefits of petroleum development in ANWR of \$2.98 billion. Alternatively, using updated oil price projections and revised tax and financial assumptions, the Arctic National Wildlife Refuge Financial Analysis Simulation Model (AFAM) projects the expected present value of net economic benefits of oil production at between \$0.32 and \$1.39 billion. Decision makers considering whether or not to open ANWR to petroleum development can use these values to judge if the economic benefits outweigh the projected negative wilderness and wildlife impacts. (Edited author abstract) 10 refs.

**077547 LEGAL AND TAXATION IMPLICATIONS FOR THE ACQUISITION AND DISPOSAL OF OFFSHORE PETROLEUM PRODUCTION AND EXPLORATION TENEMENTS - A PRACTICAL VIEW AND UPDATE.** The administrative aspects of petroleum mining and exploration companies have become more complex of recent years. One area where this is particularly so is in relation to the livelihood of the industry, i.e. access to tenements. Recent amendments to the Petroleum (Submerged Lands) Act, and associated Acts, and proposed new tax imposts (e.g. cash bonus bids, retention licence fees, resource rent tax, and capital gains tax) in relation to the offshore segment of the industry have added significantly to the complexities in planning the acquisition and disposal and ongoing control of tenements. Each of these is examined individually and in conjunction for the benefit of planners and executives administering tenements within their organisations. (Edited author abstract)

Allen, J. (Allen Allen & Hemsley, Sydney, Aust); Williamson, M. *APEA J* v 26 pt 1 1986, 1986 APEA Conf, Adelaide, Aust, Apr 7-9 1986 p 7-21.

**077548 DEREGULATION OF THE AUSTRALIAN OIL MARKET.** In late 1984 the Government decided, after an extensive review, to partially deregulate immediately and to move to a substantially deregulated domestic oil market by 1988. After only four months of the new arrangements the Government announced a further review claiming that changes in international and domestic market conditions had led to calls from the industry to accelerate the move to deregulation. Deregulation would directly affect the prices and consumption patterns for domestic crude oils. The diverse positions taken during the mid 1985 review reflected differing assessments of the consequences of deregulation and differing impacts on interested parties. The Government decided to halt the move toward deregulation but to review the position again in 1987. (Edited author abstract)

Hart, G.E. (CSR Ltd, Sydney, Aust). *APEA J* v 26 pt 1 1986, 1986 APEA Conf, Adelaide, Aust, Apr 7-9 1986 p 54-65.

**077549 ALIENATION OF LAND FROM EXPLO-**

**RATION - A SOUTH AUSTRALIAN EXAMPLE.** Access to the land surface for exploration is vital if the state's subsurface resources are to be discovered and developed. Over the past ten years, however, there has been a major increase in limitations on access to land for exploration in South Australia. Less than 0.1 per cent of the area of the state has been directly involved in resource exploration and development. Despite this, and despite successful introduction of codes of practice to limit the effect of exploration activities and to speed rehabilitation of access tracks and drillsites, the industry is generally and erroneously perceived to be a major land user. This is evidenced in community attitudes and reflected in recent legislation. (Edited author abstract) 6 refs.

Laws, R.A. (South Australian Dep of Mines & Energy, Parkside, Aust). *APEA J* v 26 pt 1 1986, 1986 APEA Conf, Adelaide, Aust, Apr 7-9 1986 p 73-87.

**077550 FOREIGN FUNDING OF THE AUSTRALIAN PETROLEUM INDUSTRY - IMPORTANT ASPECTS OF THE DIRECT INVESTMENT DECISION PROCESS.** The paper provides an outline of the financial aspects of the foreign direct investment decision process and an understanding of how this can help attract funds for Australian petroleum exploration and development. The techniques in assessing country risk are reviewed, and the methodology of international banks assessed. The Go/No-Go, Premium for Risk, Range of Estimates, and Risk Analysis techniques are described. In considering the forecasting of exchange rate movements it is recognized that, while there is no adequate forecasting measure, the major variables of comparative prices, interest rates, and comparative money supply require attention. (Edited author abstract) 10 refs.

McKee, J. (Petroleum Management Associates Pty Ltd, Unley, Aust). *APEA J* v 26 pt 1 1986, 1986 APEA Conf, Adelaide, Aust, Apr 7-9 1986 p 88-95.

**077551 RECENT CHANGES TO AUSTRALIA'S OFFSHORE PETROLEUM REGIME.** A practical consequence of the Offshore Constitutional Settlement for the industry is that many offshore titles are now being split into two separate titles - one under State legislation within the three-mile territorial sea and the other under Commonwealth legislation for the Adjacent Area beyond the territorial sea. The Commonwealth proposal to introduce cash bonus bidding for highly prospective offshore exploration permits after being defeated in the Senate in the first half of 1985 was subsequently passed in November 1985. An APEA proposal for the introduction of a new form of title under the Petroleum (Submerged Lands) Act (PSLA) to protect currently non-commercial reserves has been adopted by legislation. Some recommendations are given for establishing a more secure and certain system of title under the PSLA and to minimize the current administrative delays being experienced by industry. (Edited author abstract)

Reid, P.C. (Esso Australia Ltd, Sydney, Aust). *APEA J* v 26 pt 1 1986, 1986 APEA Conf, Adelaide, Aust, Apr 7-9 1986 p 102-104.

**077552 AUSTRALIAN OIL INDUSTRY - TWO YEARS OF FLOOD BEFORE THE PERMANENT DROUGHT.** Australia has achieved 100 per cent self-sufficiency in crude oil, but a substantial increase in exploration activity is required if a major fall in self-sufficiency is to be averted after Bass Strait peaks in 1987. Browse Basin (Timor Sea) disappointments indicate that while there will be good production from Jabiru and perhaps Challis, these will not replace the declining Mackerel, Halibut, and Kingfish fields in Bass Strait. If oil is not found the balance of payments will suffer badly. Each percentage point drop in self sufficiency will cost Australia \$85 million or nearly 0.5 per cent of exports. If domestic production falls to 470

000 barrels per day by 1990, imports of crude oil will cost \$2 billion in 1985 dollars (assuming flat oil prices). (Edited author abstract)

Story, I. (Meares & Philips Ltd, Sydney, Aust). *APEA J* v 26 pt 1 1986, 1986 APEA Conf, Adelaide, Aust, Apr 7-9 1986 p 106-122.

**J77553 TAXATION ASPECTS OF SOLE RISK, OR, HOW TO MAKE THE TAX SYSTEM WORK FOR YOU.** This paper describes the taxation implications of a sole-risk program and the taxation results that one expects to flow to a sole-risk party and a non-sole-risk party if a structure different from that now used is adopted for that program. The taxation implications will be considered under the headings of income tax, resource rent tax, and resource rent royalty. The paper will discuss how the tax system can be used to diminish the incentive for a company to allow a party to undertake a sole-risk operation.

**077554 MAINFRAME-TO-MICROCOMPUTER SOFTWARE TRANSPORTABILITY.** Most development and maintenance work on our suite of technical drilling applications is done in the mainframe environment. With microcomputers and mainframes being used to distribute the final product, special attention must be paid to the production of a 'transportable' code. This paper describes some of the problems encountered when petroleum industry FORTRAN applications are moved from a mainframe to microcomputers and outlines a development environment that facilitates mainframe-to-microcomputer software migration. (Author abstract) 4 refs.

Seehafer, John A. (Amoco Production Co). *JPT J Pet Technol* v 39 n 12 Dec 1987 SPE 15289, p 1571-1575.

**077555 OIL & COMPUTERS: EXPLORATION.** The rapid expansion of geophysical and geological applications and the great need to reduce oil and natural gas finding costs have combined to encourage exploration companies to exploit computer technology to its fullest potential. One method to exploit computers that has gained wide acceptance is known as functional analysis, which generally is creation of a multi-department, multi-discipline task force to develop goals and evaluation criteria, evaluate available systems, and guide implementation of systems once they are purchased. Texaco U.S.A.'s geoscience technology department, for instance, used its own version of this approach to define the function to be provided. The result was a switch of its mainframe architecture late last year. The same method is being used by Mobil Exploration & Producing Services Inc. to select a new seismic processing package. And at Standard Oil Production Co., functional analysis was used in combining the computer support services for the company's exploration and production strategic business units.

Hagar, Rick (Oil & Gas Journal, Tulsa, OK, USA). *Oil Gas J* v 86 n 2 Jan 11 1988 p 42, 44-46.

**077556 COMPUTER USE ROCKETS AS ENGINEERS TRADE TOOLS FOR SOFTWARE.** Innovative new software programs range from numerical procedures for accurate downhole mechanics to expert system technology, providing rules or logic for fundamental problem solving. The expert system, a phase of artificial intelligence, is a set of computer programs coupled with a database to act as a human expert. Graphics programs now are also widely used in the industry. Computer work stations are finding a place in the engineering community, as well. The work station is a combination of software and hardware. There are several types of work stations from

stand-alone systems to mainframe dependents. Work stations dovetail with another growth area - integrated hardware and software systems. These integrated systems allow a group of programs to exchange data. Another means by which to exchange and gather data is the public-access dial-up network. The role of computers in the field is discussed along with the application of computers to reservoir analysis. 2 refs.

**077557 INCORPORATING CURRENT PRICES INTO LONG-TERM ENERGY FORECASTS: A MAXIMUM LIKELIHOOD, ADAPTIVE EXPECTATIONS APPROACH.** A maximum likelihood estimation procedure is applied to a simple adaptive expectations model of historically based long-term energy price forecasting to evaluate the appropriate weighting of current prices. Maximum likelihood estimates for five- and ten-year forecasts are produced, along with corresponding one-standard-deviation dispersions, and compared with both the ordinary least squares estimates prepared by Manne and Schrattenholzer (1986b) and the 1985 IEW Poll responses. Disagreement across poll respondents seems to understate the uncertainty reflected in efficient forecasts derived from historical price data. The averages of the poll responses are, in addition, higher than the corresponding likelihood estimates. (Author abstract) 7 refs.

Yohe, Gary W. (Wesleyan Univ, Middletown, CT, USA). *Resour Energy* v 9 n 2 Aug 1987 p 141-152.

**077558 OPEC'S RETURN TO FIXED OIL PRICING.** The system of international oil pricing has moved from one extreme to the other. It has either been very rigid, based on a market crude with a fixed relative price for all other crudes (i.e., fixed price differentials) or floating prices with each country free to set its price and output level. It is possible, however, to conceive of a pricing system that is responsive to the market forces, while providing control and avoiding chaos. Such a system would have a better chance of success than the highly inflexible system of fixed prices. In the paper this possibility is discussed and a conclusion presented. (Author abstract) 8 refs.

**Economics** See Also **OIL FIELDS—Offshore; PETROLEUM PROSPECTING—Wisconsin.**

**077559 PROGRAM CALCULATES VOLATILITIES OF OIL FUTURES PRICES.** A program for an HP-41CX calculator has been developed that calculates the implied volatilities of commodity futures prices, including those for oil. Such data are useful to the oil industry for improving inventory strategies, the hedging of risk, and the evaluation of investment alternatives. The iterative program to solve for the expected volatility ( $v$ ) presumes that the exercise price, the expiration date of the option, the price of the option, and the price of the underlying futures are entered in that order. The assumptions on which the program is based are discussed, and the program and an application example are given. 3 refs.

**077560 ENERGY AND ECONOMIC PROBLEMS IN THE OIL PATCH.** Among the most prominent effects of the energy industry's problems including record decline of oil prices and downturn of the energy industry,

are those revealed in business and bank failures. The 10 oil producing states surveyed are Alaska, California, Colorado, Kansas, Louisiana, New Mexico, North Dakota, Oklahoma, Texas and Wyoming. Economic indicators in the study included business failures, bankruptcy filings, unemployment rates, rotary drilling rig counts, reported drilling well completions, crude oil production rates and bank failures. Business failures continue to be heavy in the West South Central Region - which includes Texas, Louisiana, Oklahoma and Arkansas.

**Employee Training**

**077561 PROCESS SIMULATORS FOR OIL- AND GAS-PLANT OPERATORS.** Process simulators have been used for some years in the oil and gas industries. As a training device, the simulators allow the trainee to perform plant or platform operations under normal and abnormal conditions without risk to personnel, equipment, or production. Startup and commissioning phases of new plants and processes are shortened and proceed more smoothly because tasks have been rehearsed through simulation. This paper describes how simulator systems have been successfully integrated into an operator training program. (Author abstract) 2 refs.

**Land Reclamation**

**077563 MULTIPLE LAND USE - AN ESSENTIAL PART OF ENVIRONMENTAL PLANNING.** The Australian petroleum industry has been involved in environmental planning and has developed an awareness of multiple land use over the past twenty-five years, more particularly over the past decade. This is in accord with the World Conservation Strategy and the National Conservation Strategy for Australia upon which the Australian State and Territory conservation strategies are based. As the term implies, multiple land use means a sharing of the land. The range of uses includes reserves, heritage areas, agriculture, urban and suburban development and mining. This paper deals primarily with the restoration of the existing environment. Restoration is achieved by preserving, to the greatest extent possible, the vegetation and topsoil which are stripped from the development area. (Edited author abstract) 2 refs.

Butler, W.H. (Dinara Pty Ltd, Perth, Aust). *APEA J* v 25 pt 1 1985, APEA Conf: Tech Pap, Perth, Aust, Mar 24-27 1985 p 311-315.

**Legislation** See Also **PETROLEUM PROSPECTING—Australia.**

**077564 CAPITAL GAINS TAX IN THE PETROLEUM INDUSTRY.** Federal Labor Government has announced its intention to incorporate into the Australian

fiscal scene a capital gain tax. The tax is to be levied at marginal and corporate income tax rates on 100 per cent of inflation adjusted gains realised on assets acquired on and after 20 September 1985. There are substantial areas of uncertainty in the capital gains tax proposals generally, and in particular as they relate to the petroleum industry. The capital gains tax proposals outlined to date deal, superficially, with basic and very tangible property. (Edited author abstract)

Losses

**077565 OIL LOSS, MEASUREMENT AND CONTROL.** Absolute accuracy in measurement is not achievable - it would be impossibly costly to even try. Oil loss is however important and a choice of appropriate measurement methods is essential, and the points at which they should be applied if the results are to have best effect for the expenditure involved. It is the purpose of this paper from the experience of others to highlight those areas of loss which are most significant compared with others where investment for reduction is less likely to pay out. 4 refs.

Anon (Inst of Petroleum, London, Engl). *Q J Tech Pap Inst Pet* Apr-June 1986 p 3-51.

**077566 COMPUTER AIDED LOSS INVESTIGATION AND MONITORING.** Computer aided loss control is particularly applicable for complex product distribution systems, where there are mixtures of static and dynamic measurements, continuous and batch transfers, long interterminal pipelines. Computer statistical analyses of historic data distinguishes between the relatively small systematic errors and the larger errors. Individual and overall measurement uncertainties can be readily estimated. Computer graphic display of control charts assist in the monitoring of individual plant and overall system reconciliation and in the interpretation of the results. (Edited author abstract).

**Marketing** See Also ENERGY RESOURCES—Economics.

**077567 PRICE OF OIL: LOWER AND UPPER BOUNDS.** The magnitude of the recent dramatic fall in oil prices has once again (like the rises of 1973 and 1979) taken most energy analysts and oil industry participants by surprise, creating even greater uncertainty about future developments in the oil market. We suggest that a return to first principles is appropriate at this time in order to help clarify the outlook. Two simple Hotelling-type models of the oil market are described - one of the perfectly competitive market, the other of a purely monopolistic market. These two models are used to derive lower and upper bounds on oil prices. A reinterpretation of the history of the oil market over the last 25 years is suggested, with some implications for the future course of oil prices. (Edited author abstract) Refs.

Morrison, Michael B. (Shell Int Petroleum Co, London, Engl). *Energy Policy* v 15 n 5 Oct 1987 p 399-407.

**077568 EXTERNAL DEBT AND OIL PRICES: SOME PROSPECTS FOR OIL-EXPORTING DEVELOPING COUNTRIES.** This article examines the extent to which selected oil-exporting developing countries can continue to depend on their major source of hard currency earnings to service their external debt in particular and to promote the process of future economic growth in general. The four countries under consideration are: Ecuador, Egypt, Indonesia and Nigeria. Incorporated into the study are alternative sets of assumptions regarding future oil output, export potential, future oil prices, external debt levels and future interest rates. Both the effects of the recently formulated Baker Plan and the collapse of oil prices are examined within this context.

Personnel

**077569 OVERSEAS RECRUITING IN THE OIL AND GAS INDUSTRY - A CASE STUDY.** Early in 1982 CSR Limited established an Oil and Gas Division. By 1983 this Division had recruited twenty-six overseas technical personnel mainly from Canada and the United Kingdom. The Company needed to recruit overseas because the skills required were not available in Australia. During 1983 a review of the recruitment and settlement of these personnel and their families was undertaken. The objectives of this review were to: (i) improve the Company performance in the recruitment, induction and settlement of overseas recruits and their families; (ii) increase the likely 'length of stay' in Australia of overseas recruits and their families; (iii) address specific problems faced by recruits and their families in settlement in Australia. In depth interviews were conducted with twenty-one of the twenty-six recruits and their families using a structured interview format. (Edited author abstract)

Reviews

**077570 DEVELOPMENTS IN THE OIL REFINING AND PETROCHEMICAL INDUSTRIES.** The purpose of this paper is to review some of the major developments in the oil and petrochemical sectors and to speculate as to how the industries will develop over the next decade. Much of the substantial capacity surplus which was a problem to the oil refining and petrochemical industries during the 1970s and 1980s has been eradicated. However, it is unlikely that the processes of plant closures, companies restructuring and takeovers has finished. Within the oil sector, only Exxon and Shell look secure to maintain their business structure and strengthen their positions in the next decade. The oil companies of Kuwait and Saudi Arabia are likely to continue their progress and could be Exxon's and Shell's main rivals by the year 2000. (Author abstract). Refs.

Jenkins, Gilbert (Chem Systems Int Ltd). *Pet Rev* v 42 n 498 Jul 1988 p 36-39.

**United Kingdom** See OIL FIELDS—North Sea.

**United States** See Also ECONOMICS—Computer Simulation.

**077571 LOOK AT THE STATUS OF U.S. PETROLEUM.** Use of historical occurrences of petroleum in decision-making for future exploration must be made with care. Lithology, trap style, and reservoir age of the past are not good indicators of the future in nonfrontier areas; rather, they may suggest exactly opposite conclusions. Nonetheless, detrital reservoirs continue to be significant to exploration. Subdivision of the contiguous 48 states into petroleum provinces permits the generalization of regional characteristics and evaluation of future potential. This compilation illustrates the status of U.S. oil production and its vulnerability to fluctuations in both price and availability of risk capital.

**077572 GULF COAST REFINERS GAIN ACCESS TO MORE CALIFORNIA CRUDES.** Refiners east of the Rockies, particularly Gulf Coast refiners, have gained access to eastern and central California crudes with the opening of Celeron Corp.'s All American Pipeline (AAPL). Currently, AAPL is carrying a blend of California crudes with properties similar to Alaskan North Slope (ANS). Although the blend is of moderate gravity and sulfur content, it is comprised of crudes from several fields in California that display wide variations in quality. Future deliveries east from California will be from regions with even more extremes of quality. To familiarize refiners with the crudes that will become available, some of the properties of these California crudes are discussed, along with some of the problems refiners may encounter in processing these materials.

Vautrain, John H. (Purvin & Gertz Inc, Long Beach, CA, USA); Sanderson, William J. *Oil Gas J* v 86 n 28 Jul 11 1988 p 78-82.

**077573 US PETROLEUM INDUSTRY INCREASES ITS SPENDING ON FOREIGN EXPLORATION.** The US petroleum industry is spending money on foreign exploration and drilling at a faster rate than on any other area of spending. Part of the attraction is that the dollar per acre cost for finding commercial reserves is about 50-60 percent less in the underdeveloped countries than it is in the United States. Among the resources for foreign prospects commanding a growing share of US companies' capital spending are: current oil prices; economics of many foreign exploration and development prospects are more attractive; high production costs and the lack of accessible world class structures tending to outweigh the smaller political risk in the US vs. foreign countries; with the oil price collapse, many developing nations outside OPEC are improving contract terms with foreign companies.

## Accident Prevention

**077576 METHODS TO DETECT AND CONTROL SPILLAGES IN EUROPEAN OIL LINES - PART 1.** The following report outlines and compares the preventive measures taken and the current methods used to detect spillage from cross-country oil pipe lines, together with the emergency procedures to be implemented in the event of an incident. The factors such as product, pipe line size, length and type of operation are considered to determine the most appropriate application of spill prevention methods. The requirements for a pipe line are determined during the design phase by the owner(s) or operator and must meet any regulator authority requirements. A well-designed line, fit for the purpose of its specified duty and compatible with the environment it passes through, provides the basis for an efficient and safe system.

Brown, J.R. (CONCAWE Oil Pipelines Management Group, The Hague, Neth); Bianchini, M.; Lighthart, M.; Du Payrat, C. Noel; Whitmore, J.B. *Pipe Line Ind* v 67 n 5 Nov 1987 p 56, 58, 127.

## Canada

**077577 ALBERTA PIPELINE EXPANSION, CONVERSION MOVES HEAVY OIL TO CANADIAN AND U.S. MARKETS.** Expansion of Alberta Energy Co. Ltd.'s (AEC) Cold Lake pipeline system has allowed the economic and efficient transportation of increasing volumes of heavy oil from the Cold Lake and Wolf Lake areas in Alberta to markets in Edmonton, Eastern and Western Canada, and the U.S. A comprehensive construction program was planned and implemented. The program involved construction of a 610-mm (24-in.) OD pipeline to carry bitumen blend and the conversion of the existing 323.9-mm (12.76-in.) bitumen-blend pipeline to transport diluent. Some topics discussed are the following: the expansion program; displacement and linefill; Stage 1 (Ardmore to Bellis); Stage 2 (Bellis to Edmonton); Stage 3 (MLV-17 to the terminal); fabrication and installation; mainline-valve installation; and completion and linefill.

Zboya, T.M. (Canuck GIE Engineering Ltd, Calgary, Alberta, Can); Zakowski, J.R. *Oil Gas J* v 85 n 44 Nov 2 1987 p 44-48.

## Cathodic Protection

**077578 AUTOMATED DATA KEEPING FOR CATHODIC PROTECTION SYSTEMS.** The application used Framework, a multifunction software package, and Tricorder Companion, a communications program. The hardware consists of a personal host computer housed in All American Pipeline (AAPL's) operations headquarters and tricorders used by technicians in the field. Each test site is set up as a database which is printed out in the form of a data sheet. This data sheet includes pertinent test site information such as location, test station type and a complete history of readings. The program has a feature that can plot a graph of the latest cathodic protection readings for any given section of the pipe line on any scale specified. Data entry is fairly simple and can be performed manually or automatically.

Webb, Tom (All American Pipeline Co, Bakersfield, CA, USA); Sandoval, Sandy. *Pipe Line Ind* v 68 n 6 Jun 1988 p 15-16.

**077579 METHODOICAL APPROACH KEY TO CATHODIC-PROTECTION EVALUATION.** Effective pipeline-maintenance procedures depend on a methodical approach to evaluating the cathodic-protection (CP) system and coating integrity. These procedures are critical

in reducing corrosion failures and resulting costly repairs. An evaluation should include a CP-system audit, a coating-defect survey, a CP-potential survey, an interpretation of results, and necessary remedial action. Various coating and potential survey methods currently utilized are compared and their effectiveness under differing conditions noted in this final part of a four-part series on pipeline protection. 5 Refs.

Davies, P. *Oil Gas J* v 86 n 31 Aug 1 1988 p 40-43.

## Compressor Stations

**077580 VIBRATION ANALYSIS KEY TO COMPRESSOR FOUNDATION MAINTENANCE.** Vibration results from unbalanced forces generated by the machines resting on these foundations. The stress which results from this vibration in turn leads to fatigue which causes cracking. An excellent way to investigate fatigue is through close scrutiny of maintenance and daily operating records. Any change in the operating conditions from those for which a foundation was designed can nullify the predicted performance of the foundation, nullify the initial design computations and lead to excessive vibration, the shortening of fatigue life, and the eventual failure of the foundation. This article discusses foundation cracking, oil seepage, multiple compressors, sand cushion and rock foundations, and other aspects of the subject. 11 Refs.

Watson, W.D. (Watson & Associates, Midland, TX, USA). *Oil Gas J* v 86 n 32 Aug 8 1988 4p.

## Computer Applications

**077581 BATCH TRACKING REFINED PRODUCTS BY COMPUTER.** Explorer Pipeline's computers are configured with SCADA, batch tracking and stock accounting on the primary computer with other applications programs on the secondary. A 'watch dog' routine monitors the operation of the SCADA computer to determine its status and will automatically switch SCADA operations to the secondary computer in the event of failure. Data are continuously transmitted from the primary to the secondary via a high speed computer-to-computer data link, including dynamic batch tracking and ticket information. Once each day all data files are backed up to magnetic tape for security, recovery and historical purposes.

Mauer, Wallace J. (Explorer Pipeline Co, Tulsa, OK, USA). *Pipe Line Ind* v 68 n 6 Jun 1988 p 17-18.

## Construction

**077582 ENTREPOSE INSTALLS EGYPTIAN CRUDE TRUNKLINE SYSTEM.** The latest crude trunkline construction project to be completed is Agiba Petroleum Co.'s 166-km (103-mi) line between wells in the Meleha concession to a shipping terminal at El Hamra. Construction problems on the project resulted from the short time available to supply materials, mobilize equipment and personnel and move in and set up construction camps in the rocky western desert. Location, terrain and soil conditions also were major sources of construction problems. Corrosion protection was furnished, according to DIN 30670, by an application of fusion bonded epoxy coating, which was covered by Mannesmann polyethylene coating. Field welding was done manually using stick electrodes to join the .375-in. WT line pipe.

Lafarge, G. (Entrepose Int, Levallois-Perret, Fr). *Pipe Line Ind* v 67 n 5 Nov 1987 p 60.

**077583 UNDERSEA UNDERGROUND.** Exploitation of the Oseberg oil field in the Norwegian sector of the North Sea has produced new problems and new answers. To ensure that the line will carry safely the 600,000 barrels a day of its estimated capacity, Norsk Hydro has had to develop new welding and maintenance techniques. A remote controlled system has been evolved which represents a significant step towards introducing robot technology into deep water welding. Another first for Oseberg is the use of the newly built Petrojarl 1 production ship. Petrojarl's initial job will be to monitor the behavior of the

oil reservoir, through long-term testing of two wells, enabling better positioning of production wells for future development. A description of Phase I development of Oseberg is presented.

Anon. *Int Constr* v 26 n 12 Dec 1987 p 18-19.

## Control

**077584 TELECONTROL SYSTEM FOR A MULTI-PRODUCTS PIPELINE.** The operation of a multi-products pipeline is complex. This article describes a telecontrol system that was implemented to automate such a pipeline. (Edited author abstract) 2 refs.

Hallas, J.M. (South African Transport Services). *Elektron (Johannesburg)* v 4 n 9 Sep 1987 p 5-7.

**077585 ARCO ENSURES SYSTEM RELIABILITY.** Arco Pipe Line Co., a subsidiary of Atlantic Richfield Co., operates crude oil gathering lines, trunk lines and refined products pipelines. Movement of crude oil and products through the South and Southwest requires regulation of pipeline pump sequencing, line pressures, tank volumes and product metering. The Arco control center at Independence, Kans., is headquarters for the entire pipeline control network. The control network has three principal elements: the telecommunications system, the supervisory control and data acquisition system and the control center itself. Each is protected from a loss of power.

Anon. (Pipeline & Gas Journal, Cleveland, OH, USA). *Pipeline Gas J* v 214 n 11 Nov 1987 p 35-36.

**077586 HOW SUN PIPE LINE HANDLES MEASUREMENT MANAGEMENT.** The Eastern area supervisory control and data acquisition (SCADA) system of Sun Pipe Line Co. allows the dispatchers in Wayne, Pa. to control 1,500 mi of common carrier products pipe line having 36 delivery facilities with 187 tanks, 19 pump stations, two transfer systems and a total of 42 meters. Every hour the SCADA computer transfers data via an inter-computer link to the operations control computer. The manned locations use a remote terminal device to send their data directly to the operational control computer. The trend within SPL has been toward a higher integration in operational systems which includes scheduling, meter factor management and ticketing.

Jarvis, Larry D. (Sun Pipe Line Co, Wayne, PA, USA); Sells, Christian; Western, Philip D. *Pipe Line Ind* v 68 n 6 Jun 1988 p 22-24.

**077587 TEXAS EASTERN'S NEW SCADA SYSTEM USES DECENTRALIZED STRUCTURE FOR EFFICIENCY.** Texas Eastern Products Pipeline Co.'s new supervisory control and data-acquisition (scada) system, currently in the final stages of installation, speeds data flow and improves interaction between the operator and the pipeline system. Texas Eastern installed its first computerized scada hardware and software in 1975. The new system provides faster processing, graphics capabilities, alarm, and back-up systems necessary to enhance the pipeline's efficiency and its response to customer needs. With the SCADA system, which the article describes, Texas Eastern controls and monitors shipment of an average 414,000 b/d of refined petroleum products and LPG.

Moore, G.E. (Texas Eastern Products Pipeline Co, Houston, TX, USA). *Oil Gas J* v 86 n 32 Aug 8 1988 p 33-36, 38.

## Control Systems

**077588 DEPARTMENT OF ENERGY AUTOMATES STRATEGIC PETROLEUM RESERVES.** The U.S. Department of Energy (DOE), is automating the process control system for the major Strategic Petroleum Reserves (SPR), located along the Gulf Coast of Texas and Louisiana. Each of these crude oil storage facilities is being equipped with a Coggins Systems Series 8100 Distributed Control System. This system is programmed for automatic operation, while affording ease-of-user interface through color graphics process display terminals

(operator's terminals). Under normal operations, a single operator is able to manage an entire facility. Complex control operations require only function selection and initiation through simple keystrokes with the aid of process display menus.

Stiles, Robert E. *Pipe Line Ind* v 67 n 6 Dec 1987 p 23-24, 29.

## Corrosion

**077589 MECHANISMS AND CONTROL OF MICROBIOLOGICAL CORROSION IN PETROLEUM INDUSTRY.** Microbiological corrosion is a severe problem in the petroleum industry. Cathodic protection is usually applied for minimizing the loss of microbiologically induced corrosion. But bacteria can thrive where the potential of the system is less than  $-0.85V$  vs  $Cu/CuSO_4$  electrode. In this review article, the mechanisms of microbiological corrosion of mild steel, stainless steel, aluminum alloys, copper alloys and cathodically protected pipelines have been described in detail. Procedures have been outlined for the location of microbiological growth along the buried pipeline route. Various methods have been described for the control of microbiological corrosion for the onshore and offshore installations. (Edited author abstract) 18 refs.

Chatterjee, S.S. (Project & Development India Ltd, Dhanbad, India); Banerjee, K.C. *Key Eng Mat* v 20-28 pt 1-4 1988, 10th Int Congr on Met Corros, Madras, India, Nov 7-11 1987 pt 1, p 717-726.

## Corrosion Protection

**077590 PIPELINE PROTECTION - 1. COMBINATION OF CORROSION-SURVEY METHODS IMPROVES PROTECTION.** Combining the three most widely used above-ground-survey procedures for evaluating coating integrity and cathodic protection adequacy can overcome the technical and economic penalties of choosing a single survey method. A review of each method and of several case histories shows how the procedures complement each other. 4 refs.

Allen, M.D. (Spencer & Partners, London, Engl); Barnes, N.R. *Oil Gas J* v 86 n 9 Feb 1988 p 59-60, 62-64.

**077591 COATINGS TO RETROFIT IN-SERVICE PIPE LINES.** Repairing coating failures on in-service lines, which are caused for several reasons, can be accomplished with time-consuming and expensive procedures. The authors describe how a new two-part coating system has been used successfully on several locations. They also describe how retrofitting coatings on loaded lines can be easily accomplished. 2 refs.

## Design See PIPELINES—Offshore.

## Earthquake Resistance

**077592 DESIGNS FOR BURIED PIPELINE CAN REDUCE SEISMIC HAZARDS.** Pipelines usually cross a variety of soil conditions, some of which could pose a danger when subjected to seismic movement. The more common ground-failure hazards associated with seismic events, including faults, liquefaction, densification, and landslides are discussed in this article. Current design practices to limit seismic damage include locating the pipeline away from active faults, steep hillsides, and soft soils; increasing the flexibility of the system by use of more ductile materials and providing "fail-safe" systems at sites where damage may be anticipated. 15 refs.

Whitelaw, Joseph A. (Southern Pacific Pipe Lines Inc, Los Angeles, CA, USA); Reppond, Dennis W. *Oil Gas J* v 86 n 42 Oct 17 1988 7p.

## Economics

**077593 SCIENCE, ENGINEERING AND ECONOMICS: OR AT THE INTERFACE.** Engineers designing submarine oil-pipeline systems for the Beaufort Sea need to know how deep to bury them. Scientists studying ice scour have a major input into this decision; so do the economics of burying and pipeline failures. An operational researcher was asked to examine the way these aspects can be treated and the way they can be fitted together. This paper describes the resulting study, to illustrate how operational research might help in other interfacing contexts. (Author abstract) 11 refs.

Chapman, C.B. (Univ of Southampton, Engl). *J Oper Res Soc* v 39 n 1 Jan 1988 p 1-6.

## Environmental Impact

**077594 SOCIOENVIRONMENTAL IMPACTS OF PANAMA'S TRANS-ISTHMIAN OIL PIPELINE.** The Trans-Panama Oil Pipeline is an illustrative case study of environmental mismanagement. The project was approved and completed in 1981-1982 before submission of an environmental impact assessment. The environmental studies are seriously flawed by a number of omissions. Baseline studies of petroleum hydrocarbons in the marine ecosystems were not performed. Serious attention was not given to the possibility of a land spill or degradation of terrestrial ecosystems. The socioeconomic considerations of locating the pipeline and adjacent road through the watershed of a major hydroelectric project, as well as through the homelands of the Guaymí Indians, were ignored. As national planners guide the development of Panama's infrastructure, they can ill-afford to continue to ignore social, economic, and environmental considerations. (Author abstract) 58 refs.

Suman, Daniel O. (World Coll West, Petaluma, CA, USA). *Environ Impact Assess Rev* v 7 n 3 Sep 1987 p 227-246.

## Expansion Joints

**077595 RUBBER EXPANSION JOINTS.** Pipeline dynamics can create stresses and strains that may cause damage ranging from aggravating minor leaks at the flanges to major ruptures that require lengthy service interruptions and repairs. Rubber expansion joints and pipe connectors provide flexibility that protects pressurized systems from damage caused by the almost constant movement in piping systems. A flexible expansion joint also acts as an efficient isolator that absorbs vibration and deadens noise as well as compensating for minor misalignment of pipeline sections.

Magner, Ray (Vibration Mountings & Controls Inc, Bloomington, NJ, USA). *Pipeline Gas J* v 215 n 3 Mar 1988 p 30, 32-33.

## Failure

**077596 PETROLUL PIERDUT PRIN DEFECTELE CONDUCTELOR. [Oil Losses Due to Pipeline Failure].** During the oil pipeline transport certain failures may occur through which oil or oil products are leaking to the surface. The presence of porous media over a pipeline failure reduces the leakage rate through an orifice, as compared to the situation when the same orifice would be open. (Author abstract) In Romanian. 3 refs.

Stan, Al. D. (Inst de Petrol si Gaze Ploiesti, Rom). *Mine Pet Gaze* v 38 n 3 Mar 1987 p 147-149.

**077597 NORTHEAST U.S. PRODUCTS LINE UPGRADED AFTER MAJOR LINE BREAK.** Failure at the toe of the fillet weld of a full encirclement repair sleeve resulted in a major petroleum-product spill in a heavily populated and traveled part of the Eastern U.S. The first indication of this was at 9:55 a.m., Oct. 7, 1986, when the recording charts at Sun Pipe Line Co.'s Twin Oaks, Pa., pump station indicated a pressure drop and a flowrate increase on the 14-in., east line high-pressure petroleum-products pipeline. At 10:04 a.m., the line was

shut down. An investigation of the failure and cause led Sun Pipe Line Co. to remove all sleeves which had been installed on its 14-in., 110-mile East Line. A project-management team was assembled and a shutdown of the entire line to complete the repairs was organized. During the 36-day shutdown, 97 sleeves were located and removed, 19 mainline valves were reconditioned, and other line improvements made at a cost of nearly \$6 million.

Cross, T.F. (Sun Pipe Line Co, Wayne, PA, USA); Robertson, C.A. *Oil Gas J* v 86 n 7 Feb 15 1988 p 35-38, 40.

## Flow

**077598 NEW PRESSURE-DROP, HOLDUP EQUATIONS AGREE WITH FIELD DATA.** New equations for pressure drop and holdup in a two-phase pipeline not only show good agreement with a broad range of large-diameter data but also can be easily applied. These equations are based upon a fundamental model for both pressure drop and liquid holdup. And they are compared to large-diameter field data encompassing a wide range in operating parameters. 11 refs.

Barnette, John A. *Oil Gas J* v 85 n 52 Dec 28 1987 p 103-104, 106-108.

**077599 SLURRIES AND EMULSIONS OF WAXY AND HEAVY CRUDE OILS FOR PIPELINE TRANSPORTATION OF CRUDE OIL.** The high viscosity of many asphaltic crude oils and the high pour points of many waxy crude oils present significant problems in their transportation over long distances by pipeline and tanker. A possible solution which we have studied in the laboratory is the emulsification or dispersion of the oil in water or brine so that shear takes place in the continuous aqueous phase rather than the oil droplets or particles. Synthetic waxy crude oils were prepared by dissolving paraffin wax in white mineral oil at slightly elevated temperatures and then measuring the pour point. One containing 30% wax had a pour point of 43°C and was selected for preparations of the dispersions. This was emulsified in water at a temperature higher than the pour point by using a suitable surfactant as an emulsifying agent. (Edited author abstract) 5 refs.

Marsden, S.S. (Stanford Univ, Stanford, CA, USA); Ishimoto, Kiyoshi; Chen, Lidian. *Colloids Surf* v 29 n 1 Jan 15 1988, Emulsification and Demulsification, Apr 1986 p 133-146.

## Heating

**077600 SOME CONSIDERATIONS ON A NEW OIL TRANSPORTING SYSTEM USING THE MAGNETIC COAXIAL PIPE.** A discussion is made on a new oil transporting system using magnetic coaxial pipe concerning its electrical characteristics and the experimental results on a 150m length test pipeline. When magnetic coaxial pipe is used as a heater, the heat generation occurs uniformly and the voltage of the outside of the coaxial pipe is sufficiently low to be electrically safe even when the frequency is low. This system is applicable to long distance submarine pipelines. 2 refs.

Hojo, H. (Nippon Kokan KK, Kawasaki, Jpn); Nagamune, A.; Murakami, K. *IEEE Trans Magn* v MAG-23 n 5 Sep 1987, INTERMAG '87: Int Magn Conf, Tokyo, Jpn, Apr 14-17 1987 p 3281-3283.

## Inspection

**077601 INTELLIGENT PIGS PROVE VALUABLE.** Pipeline operators in various parts of the world are beginning to evaluate a service for locating corrosion and mechanical damage in high-pressure oil and gas pipelines. Originally developed by British Gas to inspect its domestic U.K. gas pipeline network, the technique of using intelligent pigs with onboard processing computers to pinpoint flaws is commercially available to pipeline operators both onshore and offshore. The full range of pigs covers pipelines between 8- and 48-in.

Shannon, R.W.E. (British Gas plc, Cramlington, Engl).

Pipeline Gas J v 214 n 10 Oct 1987 p 14-16.

**077602 FLUX-LEAKAGE VEHICLES PASS TESTS FOR PIPELINE INSPECTION.** Tests of pipeline-inspection equipment based on principles of magnetic flux leakage have shown it to be capable of routine maintenance and to provide technical and economic advantages over hydrostatic testing. The equipment accurately locates and describes metal-loss defects and enables a pipeline's condition to be determined before a feature becomes critical. Further, equipment capable of detecting and sizing a range of different stress-corrosion cracking (SCC) geometries and types has also been developed and prototypes successfully evaluated during live gas tests in operating pipelines. The article discusses two additional vehicle systems developed by British Gas plc at its On Line Inspection Centre. The vehicles can detect and size external stress-corrosion cracking and survey offshore pipelines for weight-coating damage or loss of seabed cover. They have reached the prototype development stage and are currently undergoing performance evaluation in operating pipelines. 8 Refs.

#### Instrumentation

**077603 ELECTRICAL AND INSTRUMENTATION FEATURES OF THE CORTEZ AND CHOCTAW CO<sub>2</sub> PIPELINES.** Pipelines transporting CO<sub>2</sub> to crude-oil-producing fields for tertiary recovery injection are a relatively novel segment of the pipeline industry. An affiliate of the Shell Oil Company has participated in two major pipelines for this service. The electrical and instrumentation features of these pipelines are discussed. 1 ref.

Wilson, J.E. (Shell Oil Co, Houston, TX, USA); Bried, Frederick. *IEEE Trans Ind Appl* v 1A-23 n 6 1987 p 1077-1083.

#### Insulation

**077604 INSULATING GATHERING LINES.** A California pipeline contractor relied on its 40 years of experience to meet an unusually tight deadline on job. Isotherm Co. Inc., Bakersfield, installed more than 1 million linear ft of fiberglass pipe insulation on 2- and 3-in. crude oil gathering lines at the Belridge oil field in Kern County, Calif. The project, which involved insulating 200 miles of pipeline, was completed in 7 months. ?

**Interface Separation** See ELECTROSTATICS—Electric Charge.

**Laying** See Also PIPELINES, SUBMARINE—Earthquake Resistance; PIPELINES, SUBMARINE—Laying.

**077605 SEA-BOTTOM FORCES CRUCIAL IN PIPELINE CROSSINGS DESIGN.** Designing for sub-sea pipeline installation in certain regions of the world often implies crossing several existing pipelines or cables in operation. Careful attention to such contingencies can ensure a safe and a cost-effective installation. Economical and safe design of submarine pipeline crossings varies with the environmental conditions, pipeline characteristics, and construction means. The purpose of the article is to focus on the fundamental points of design. 11 refs.

Friedmann, Yves (Omnium Technique des Transports par Pipelines, Montreuil, Fr). *Oil Gas J* v 86 n 26 Jun 27 1988 p 47-50, 52-53.

#### Leak Detection

**077606 MAJOR PIPELINE INSTALLS SYSTEM TO PINPOINT LEAK SIZE, LOCATION.** Williams Pipe Line Co.'s recently installed leak-detection system can provide full time early warning protection. It is based on a modeling system whose software package lies at the heart of the leak-detection scheme. This paper describes

the equipment developments, operating constraints and modeling techniques used for this project.

**Legislation** See PIPELINES—Environmental Impact.

#### Maintenance

**077607 METHODS TO DETECT AND CONTROL SPILLAGES IN EUROPEAN OIL LINES - PART 2.** This concluding installment discusses more design and construction features for liquid lines that will reduce spillages. Design features, leak detection and other preventive measures minimize environmental damages. Emergency measures to minimize such damages are presented.

Brown, J.R. (Concawe Oil Pipelines, The Hague, Neth); Bianchini, M.; Ligthart, M.; du Payrat, C. Noel; Whitmore, J.B. *Pipe Line Ind* v 67 n 6 Dec 1987 p 30-32.

**077608 PIPELINE REPAIR SYSTEM TESTED IN ENGLAND.** To enable divers to gain longer work periods with improved protection during emergency pipeline repairs, engineers at the Engineering Research Station of British Gas plc (ERS) have conducted trials on the use of protective cofferdams that would be sunk into the seabed around the pipeline. The work was carried out to support the offshore activities of the exploration companies of British Gas. Once each cofferdam is in place, seabed materials, including pipeline cover, are removed from the inside to leave the diving teams with an accessible pipeline inside an enclosure protected from tides, currents, and shifting seabed materials. RS consulted dredging specialists, Alluvial Mining Ltd., who offered the use of a jet pump based on their AMROD remotely operated dredge to remove the seabed materials.

Anon. *World Dredging Mar Constr* v 23 n 11 Nov 1987 p 26-27.

#### Materials

**077609 FIBERGLASS LINE PIPE REQUIRES SPECIAL CARE.** Following a brief discussion of the methods for manufacturing fiberglass line pipe, the author examines joining methods, pipe design, cyclic pressure service and in-service failures. Factors that warrant consideration when installing fiberglass pipe are outlined. Operation of fiberglass systems is also briefly discussed.

Oney, Charles L. (Cities Service Oil & Gas Corp, Tulsa, OK, USA). *Pet Eng Int* v 59 n 11 Nov 1987 p 34-36.

**Mathematical Models** See Also PETROLEUM, CRUDE—Rheology.

**077610 IMPROVED MODEL FOR START-UP OF PIPELINES CONTAINING GELLED CRUDE OIL.** A sophisticated model has been developed to predict the time necessary to start-up and clean-out a pipeline full of gelled crude oil after an operational or emergency shut-down. Velocities and pressures were obtained, using the momentum and continuity equations, as a function of time, radial and axial positions. It was found that the model predicts clearing times significantly shorter than the simple model of Sestak. Further, the model can determine if compressible gels with high yield stress can, in fact, be cleared from the pipeline. Thus, the algorithm provides much more insight into the problem than the earlier work. (Edited author abstract) 11 refs.

Cawkwell, M.G. (Univ of Toronto, Toronto, Ont, Can); Charles, M.E. *J Pipelines* v 7 n 1 Nov 1987 p 41-52.

#### Measurements

**077611 HOLDUP, PRESSURE-LOSS CALCULATIONS CONFIRMED.** This final Part of three articles concludes comparisons of performances of several pressure loss and holdup correlations, including those proposed in Part 1 (OGJ, Mar. 14, p. 55), against field data taken from two large-diameter gas and gas-condensate

pipelines. This comparison began in Part 2 (OGJ, Mar. 21, p. 78). The comparison refers to the Marlin Pipeline, a 107-km (65-mile), 20 in. line with a liquid/gas ratio of 360 cu m/MMcu m (65 bbl/MMscf). 10 refs.

Baker, A. (Baker Jardine & Associates, London, Engl); Nielsen, K.; Gabb, A. *Oil Gas J* v 86 n 13 Mar 28 1988 p 44-46, 48, 50.

#### New York

**077612 PROPANE PIPELINE RESTORATION.** When Texas Eastern Products Pipeline determined it needed to rehabilitate a 165-mile segment of an 8-in. liquid propane pipeline between Watkins Glen and Selkirk, N.Y., the company was faced with a dilemma. The problem was how could propane deliveries to two of the system's common-carrier terminals be continued during the repair period. The article describes the solution.

**Nondestructive Examination** See OFFSHORE STRUCTURES—Nondestructive Examination.

**Offshore** See Also PIPELINES, SUBMARINE—Insulation; TUNNELS AND TUNNELING.

**077613 FIRST OIL PIPELINE TO NORWAY CROSSES NORWEGIAN TRENCH.** Norsk Hydro has laid the first oil pipeline from North Sea fields to Norway last summer as part of the Oseberg transportation system. The line was hydrostatically tested last fall in preparation for start-up next year. This article discusses the trench crossing approach tunnel, storage caverns, repair system, and other aspects of the subject.

Johnsrud, Paul (Norsk Hydro AS, Oslo, Norw). *Oil Gas J* v 86 n 18 May 2 1988 4p between p 35-42.

**077614 PIPELINES FOLLOWING EXPLORATION IN DEEPER GULF OF MEXICO.** Gulf of Mexico pipeline construction has been falling off sharply for shallow-water areas, while construction for middle-depth and deepwater areas has been holding steady. These trends are evident from analyses of 5-year data compiled by the U.S. Department of Interior (DOI) Minerals Management Service (MMS). This article continues a series of updates based on MMS gulf-pipeline data. These installments track construction patterns in water depths, diameter classifications, and mileage. The figures are also evaluated in terms of pipeline-construction cost data published in *Oil & Gas Journal's* annual Pipeline Economics Reports.

True, Warren R. *Oil Gas J* v 86 n 27 Jul 4 1988 p 27-32.

**077615 PIPELINES FOR SUBSEA OIL AND GAS TRANSMISSION.** Pipelines in some form or other are the essential link between offshore oil and gas production facilities and the onshore users. Be they seabed, seabed trenched, interfield, onshore transport, or transport to offshore loading facilities, all operations are dependent on the effectiveness and integrity of the transmission pipeline. Fifteen years experience in the North Sea has seen in excess of 150 subsea oil and gas pipelines installed in the UK sector extending for a total length exceeding 4000 km. At the time of writing, no hazard or incident has arisen from these installations. An overview of the important technical issues that need to be considered to ensure safe design, installation, and operation of pipelines for North Sea service is presented. (Author abstract). 33 Refs.

## Protection

**077617 METHODS OF PREVENTION, DETECTION AND CONTROL OF SPILLAGES IN WEST EUROPEAN OIL PIPELINES.** This report reviews the causes of spillage from operating cross-country oil pipelines and discusses the current practice in spillage prevention, detection and control. Performance data for the past fifteen years shows that the rate of spillage has continued to be extremely low. Data on spillages is recorded by CONCAWE and this knowledge assists in the continuous efforts to improve on the performance and minimise the effects on the environment. Spillages are prevented by competent design, careful construction, rigorous inspection and efficient operation. (Edited author abstract) 1 ref.

Bown, J.R. (CONCAWE); Bianchini, M.; Lighthart, M.; Noel du Payrat, C.; Whitmore, J.B. *Q J Tech Pap Inst Pet* Oct-Dec 1987 p ia-23.

## Protective Coatings

**077618 PIPELINE COATING PERFORMANCE - FIELD EXPERIENCE OF AN OPERATING PETROLEUM COMPANY.** The performances of various kinds of coatings used to protect buried and offshore pipelines and risers are presented through case histories experienced by the authors' company. Bituminous enamels, tapes and heat-shrinkable sleeves, polyethylene, fusion bonded epoxy polyamide, polymer cement compounds, glass fiber reinforced epoxy, and rubbers are the coating families considered. The general behavior and failures or problems encountered are reviewed for each. Current choices and future trends for pipeline coating selection are given in relation to laying and operating conditions. (Edited author abstract) 31 refs.

Roche, M. (Soc Natl Elf Aquitaine, Paris La Defense, Fr.); Samaran, J.P. *Mater Perform* v 26 n 11 Nov 1987 p 28-34.

**077619 METHOD TESTS EFFECTS OF HEAT ON FBE PIPELINE COATINGS.** A new procedure for testing elevated-temperature cathodic disbondment (C.D.) in fusion-bonded epoxy (FBE) pipeline coatings appears consistent and reliable. Further, its results question C.D. theories that fail to account for effects at above-ambient temperatures. The work to develop this procedure also included experiments that demonstrated how the relative performance of coating systems - especially FBE line-pipe coatings operated at elevated temperature - could not be predicted from ambient-temperature assessment. 9 refs.

Higgins, G.L. (Ardrox Pyrene Ltd, Iver, Engl); Bates, C.R. *Oil Gas J* v 86 n 25 Jun 20 1988 p 62-65.

## Pumping Stations

**077620 SEMIOPTIMAL CONTROL OF UNSTEADY LOAD-NODE REGIMES FOR OIL-PUMPING STATIONS.** A solution is proposed for the multicriterion problem of optimizing transient-regime control for load nodes of an electric-drive oil-pumping station, allowance being made for the hierarchy and variation of objective conditions. A method is indicated for coordination of inconsistent optimality criteria; a realization is shown for coordinate-parametric control with the aid of a regulator having variable structure. (Author abstract) 9 refs.

Borisov, R.I.; Kostyshin, V.S. *Power Eng (New York)* v 25 n 4 1987 p 112-115.

## Repair

**077621 MODELS AID PIPELINE-REPAIR WELDING PROCEDURE.** Improved welding procedures to repair a pressurized pipeline can now be designed with the use of computer models of the welding process. These procedures can reduce the chances of burnthrough or heat-affected zone cracking. The models were developed by Battelle Columbus Division from research sponsored by several major petroleum liquids and natural-gas pipeline operating companies. The key to correct design of procedures for welding on live pipelines as embodied in the Battelle project was the computer modeling of the heat input and heat dissipation associated with the welding process. Two models were developed, one for the fillet weld joining the end of a full-encirclement sleeve to the carrier pipe and one for the groove weld around a branch pipe to carrier pipe juncture. 8 refs.

Keifner, John F. (Battelle Columbus Div, Columbus, OH, USA); Fischer, Robert D. *Oil Gas J* v 86 n 10 Mar 7 1988 p 41-47.

## Research

**077622 PETROLEUM PIPELINE RELATED RESEARCH REVIEWED.** Multiphase production systems, pipeline erosion and corrosion, and valve testing and evaluation, are subjects of wide industry interest. This paper reviews these areas of petroleum pipeline related research. Among the topics examined are: multiphase flow; multiphase flow in risers; multiphase meters; multiphase pumping; the development of corrosion inhibitor packages and techniques for assessing them; valve development and evaluation; and factors to consider in valve selection. 5 refs.

Harrison, D. (BP Int, Sunbury-on-Thames, Engl). *Pet Rev* v 42 n 495 Apr 1988 5p.

**077623 PETROLEUM PIPELINE RELATED RESEARCH REVIEWED.** Multiphase production systems, pipeline erosion and corrosion, and valve testing and evaluation, are subjects of wide industry interest. This paper reviews these areas of petroleum pipeline related research. (Author abstract) 5 Refs.

## Scotland

**077624 PIPELINE ROUTING - EXPERIENCES FROM NORTHERN SCOTLAND.** The author, from Aberdeen University's Centre for Environmental Management and Planning, discusses the manner in which the nine major hydrocarbons pipelines in Scotland have been planned and how they affect the environment. He concludes that although there has not been a clear pipeline routing policy, one of Scotland's largest civil engineering programmes has progressed with minor impact thanks to continued negotiation and discussion between all the parties involved. (Author abstract) 17 refs.

Ryder, Alan (Univ of Aberdeen, Scotl). *Pipes Pipelines Int* v 32 n 3 May-Jun 1987 p 5-12, 13-14.

## Stresses

**077625 PREVENTIVE MEASURES TO AVERT CRUDE LINE SUBSIDENCE.** Longwall coal mining has affected Capline's 40-in. crude pipe line that operates from Louisiana to Patoka, Ill. The affects and corrective measures taken to properly support Capline during a four panel, longwall mining operation are outlined. Preventive action is focused on two distinct pipe line concerns caused by the subsidence. The first is soil friction forces acting on the surface of the line which could cause tensile failure. The second concern is ground subsidence curvature exceeding the critical bending radius of the pipe which could cause a buckling failure.

Wallace, M.R. (Shell Pipe Line Corp, Houston, TX, USA). *Pipe Line Ind* v 68 n 6 Jun 1988 p 19-21.

## Structural Analysis

**077626 PIPELINE INTEGRITY ANALYSIS AND MONITORING SYSTEM SHOWS DEFORMATION BEHAVIOR.** A pipeline analysis and monitoring system developed and field tested by Nova Corp. of Alberta has achieved close agreement between field measurements and structural simulations in its initial field tests. The system integrates measurements for displacements, rotations, pressures, and strains with finite-element structural models (FEM). It is designed for detecting, preventing, and predicting failures by identifying critical areas approaching limit states. The system is also a design tool for determining data-optimization strategies and is capable of utilizing displacement and strain measurements from various sources in the analysis. Measurements of displacements provide the best reliability for a dependable monitoring system. Measurements of strain are used in the system as verification and supplementary information. 12 Refs.

Wong, F. (NOVA Corp of Alberta, Calgary, Alberta, Can); Mohitpour, M.; St. J. Price, P.; Porter, T.R.; Teskey, W.F. *Oil Gas J* v 86 n 30 Jul 25 1988 p 86-91.

## Testing See Also NATURAL GAS PIPELINES—Testing.

**077627 PRESSURE TESTING WITH AIR WORKS FOR OIL PIPELINES.** During April 1985, Interprovincial Pipe Line Ltd. began delivery of oil through the Norman Wells pipeline. Evaluations of air for pressure testing found it to be a safe, efficient, economic, and environmentally sound medium for pressure testing oil pipelines during winter. Since this use, CSA-Z183 now accepts air as a test medium subject to a maximum pressure limitation equivalent to 90% specified minimum yield strength (SMYS) at the high point of a test section, 95% SMYS at the low point, and a minimum leak-test hold period of 24 hr. 5 refs.

Pick, A.R. (Interprovincial Pipe Line Ltd, Edmonton, Alberta, Can); Smith, J.D. *Oil Gas J* v 86 n 24 Jun 13 1988 p 44-47.

## Tibet

**077628 PIPELINE ON THE ROOF OF THE WORLD.** In a rare glimpse at pipeline technology in China, the author provides a fascinating account of the construction and operational problems of the 1,000-km pipeline which is Tibet's sole supply of various grades of fuel.

Lu, Xiaoming. *Pipes Pipelines Int* v 32 n 6 Nov-Dec 1987 p 14-15.

## Welding See WELDS—Defects.

### Additive Compounds

**077631 SET OF QUALIFICATION TEST METHODS FOR PROTECTIVE PROPERTIES OF PRESERVATIVES.** In recent decades, major attention has been given to shortening the time required to test new samples of protective materials without any loss of reliability of results. To this end, much work has been performed on the development of methods for qualification testing of individual properties of protective materials, and sets of such methods for each type of protective material. The sets of methods generally include laboratory methods for qualification testing of physicochemical properties. The authors have presented the methods for qualification testing of preservative materials that are included in the different sets of methods. Most of these methods have been metrologically certified. 7 refs.

Shirokova, G.B.; Lazarenko, V.P.; Englin, A.B. *Chem Technol Fuels Oils* v 23 n 1-2 Jan-Feb 1987 p 44-47.

**077632 NEW QUALIFICATION TEST METHODS FOR GASOLINES WITH SYNTHETIC COMPONENTS.** The test methods used to evaluate gasoline corrosivity in accordance with GOST [All-Union State Standard] 18597-73 (under conditions of moisture condensation) and in contact with saline water cannot be used for testing gasolines with alcohol components, since such gasolines separate into layers when they come into contact with water. When no water is present, corrosion damage to specimens made of various metals is so insignificant that it is impossible to differentiate gasolines with respect to their content of alcohols. Because of this situation, a new method has been developed. In this paper the authors present results obtained by this method in evaluating the corrosivity of gasolines with SCs, on specimens of the metals and alloys used in manufacturing parts for the fuel feed system in automotive vehicles. 6 refs.

Lebedev, S.R.; Burnistrov, O.A.; Kuznetsova, L.N.; Shtan'ko, G.I. *Chem Technol Fuels Oils* v 23 n 3-4 Mar-Apr 1987 p 152-155.

**077633 DETERMINATION OF CONTENT OF ACTIVE SUBSTANCE IN COPOLYMERIC POUR-DEPRESSANT ADDITIVES.** Copolymers of ethylene with vinyl acetate are effective pour-point depressants for petroleum products; these additives are usually supplied in the form of solutions in various hydrocarbon solvents. An important index of the additive quality is the content of active substance. It was proposed to determine the content of active substance by means of IR Fourier transform spectroscopy. The use of this method is subject to one limitation: There must not be any overlapping bands in the spectra of the polymer and the solvent. In view of this limitation, the authors turned their attention to the possibility of determining the content of active substance by means of high-performance exclusion chromatography. The studies were performed in a Dupont Model 8841

chromatograph with an IR detector, with  $\text{CHCl}_3$  as the eluent at a fed rate of 1 ml/min, at a temperature of  $40 \pm 0.2^\circ\text{C}$ . 3 refs.

Filippov, A.A. (All-Union Scientific-Research Inst for Petroleum Processing, USSR); Pavlovskaya, N.G.; Itsikson, L.B. *Chem Technol Fuels Oils* v 23 n 3-4 Mar-Apr 1987 p 158-159.

**077634 DETERMINATION OF METAL-CONTAINING ADDITIVES IN PETROLEUM PRODUCTS.** Results obtained in measurements of  $\rho_v$  of the model and real systems in the presence of the additive MASK [overbased calcium alkylsalicylate], which at the optimal concentration of 0.01% by weight gives the best process indexes in filter pressing. With increasing concentration of the additives,  $\rho_v$  of the model and real systems of slack wax and filtrate decreases, owing to the ionic character of the additives in solutions of the products from filter-pressing. For the determination of concentration of modifying additives in products from filter-pressing, the authors propose a graphical method. On the basis of volume resistivity, it is not only possible to determine the character of distribution of the modifier between the solid and liquid phases, but also to estimate this distribution quantitatively. 4 refs.

Additives See POLYMERS—Applications.

### Analysis

**077635 COMPONENT COMPOSITION OF OXIDIZED PETROLEUM CERESINS ACCORDING TO THE RESULTS OF ESR SPECTROSCOPY.** It has been shown by the methods of physicochemical analysis and the use of a spin probe that the oxidation of petroleum ceresins leads to the same structural transformations as in the case of the oxidation of polyethylene waxes. The resinous and waxy fractions of the ceresins differ substantially in molecular rigidity and physicochemical properties. (Author abstract) 6 refs.

### Blending

**077636 BLENDING OF HEAVY PETROLEUM FRACTIONS WITH ALCOHOLS.** The addition of methanol or ethanol in a low concentration to middle distillates and heavy petroleum fractions lead to a reduction of their apparent viscosity. The maximum decrease in viscosity was obtained by the addition of 3-6 percent by volume methanol. Achieved reduction in viscosity of blends was a function of initial viscosity of original petroleum fractions. The highest reduction in viscosity was achieved for fuel oil and petroleum residues, which were more viscous. Lowering the viscosity of fuel oil, reduced crude and the blends of vacuum residue with fuel oil and methanol would lead to an improvement in their flow properties. (Edited author abstract). 11 Refs.

### Chemical Analysis

**077637 ANALYTISCHE CHARAKTERISIERUNG VON IM PAREX-VERFAHREN VERWENDETEN ERDOELMITTELDESTILLATEN.** [Analytical Char-

acterization of Petroleum Middle Distillates Used in the Parex Process]. Two different straight-run and hydrocatalytically pretreated petroleum middle distillates have been characterized by means of mass spectrometrical family analysis, mass fragmentography and mineral oil analysis. The dominating reaction in the hydrocatalytical treatment of the straight-run products is the hydrogenation of olefinic and hetero compounds as well as of condensed aromatics. The demonstrated ring cleavage of condensed aromatics and naphtheno-aromatics is of minor importance. (Edited author abstract) In German. 9 refs.

**077638 INVESTIGATION OF NITROGEN COMPOUND TYPES IN HIGH-BOILING PETROLEUM DISTILLATES FROM SAUDI ARABIAN CRUDE OILS.** Acid, bases and neutral nitrogen compounds from high-boiling petroleum distillates were separated and further fractionated into fractions containing nitrogen compound types by HPLC on neutral alumina. Acids and bases were separated with anion and cation exchange resins respectively while the neutral nitrogen compounds were removed by complexation with ferric chloride supported on Attapulgus clay. The HPLC fractions were characterized by potentiometric titration for their basic and nonbasic nitrogen contents while infrared spectroscopy was used for the quantitative determination of major compound types present which are pyridines, pyrroles, amides, phenols and carboxylic acids. Characterization of individual nitrogen compounds was accomplished using gas chromatography and gas chromatography-mass spectrometry. The nitrogen compounds identified belong to three compound types which are pyridine, pyrrole and amide. (Author abstract) 16 refs.

**077639 CHARACTERIZATION OF ARAB BERRI (EXTRA LIGHT) CRUDE FRACTIONS WITH EMPHASIS ON KINEMATIC VISCOSITY-TEMPERATURE BEHAVIOR.** The characterization data has been obtained for Arab Berri extra light crude oil (API 46.9), which is one of the four crude oils being commercially produced by Saudi Arabia. Further, six true boiling point fractions (IBP-95°C, 95-205°C, 205-260°C, 260-345°C, 345-455°C and 455°C+) of this crude were characterized in terms of API gravity, total sulfur,  $\text{H}_2\text{S}$ , mercaptans, molecular weight, elemental analysis for total carbon, hydrogen and nitrogen, analysis of various metals and paraffin, aromatic and naphthalene contents of lighter fractions. The kinematic viscosity-temperature data have been obtained for 95°C+ TBP fractions for wide range of temperatures. 8 refs.

### Chromatographic Analysis

**077640 HYDROCARBON GROUPS TYPE ANALYSIS OF PETROLEUM PRODUCTS BY HPLC ON SPECIFIC STATIONARY PHASES.** The hydrocarbon group-type analysis of a large number of petroleum products by HPLC equipped with columns of suitable selectivity is described. An effective approach to the factors influencing the specificity of the columns was developed and stationary phases were synthesized by the products to be separated. All new phases were characterized by elemental,  $^{29}\text{Si}$  and  $^{13}\text{C}$  NMR analyses. The potential of these phases were illustrated by analysis of selected samples either of fundamental or of industrial interest. (Author abstract) 18 refs.

Felix, Guy (CNRS, Talence, Fr); Thoumazau, Elisabeth; Colin, Jean-Michel; Vion, Gisele. *J Liq Chromatogr* v 10 n 10 Aug 1987 p 2115-2132.

**077641 CHROMATOGRAPHIC PROCEDURE FOR THE COMPREHENSIVE SEPARATION AND ESTIMATION OF POLYCYCLIC AROMATIC HYDROCARBONS IN PETROLEUM PRODUCTS.** A chromatographic procedure using liquid and gas chromatography for the determination of both total and certain individual 4-6-ring polycyclic aromatic hydrocarbons from a single sample aliquot is described. The total PCA content of the sample is determined gravimetrically. This fraction is subsequently further fractionated on Sephadex LH20 to give one rich in PCA parent hydrocarbons which are determined using high-resolution capillary gas chromatography (g.c.). The compounds of interest are quantified by comparison of their g.c. peak areas with those from secondary internal standards. The results are corrected for losses occurring during the analysis by determining the recovery of an internal standard using ultraviolet (u.v.) spectroscopy. (Edited author abstract) 17 refs.

Pullen, David L. (BP, Sunbury-on-Thames, Engl); Scammells, Daniel V. *Fuel* v 67 n 2 Feb 1988 p 251-256.

**077642 CHARACTERIZATION OF VACUUM RESIDUES BY ADSORPTION CHROMATOGRAPHY AND <sup>1</sup>H-NMR SPECTROSCOPY.** The chemical compositions of, and structural types in, vacuum residues from Daqing, Shengli, Renqiu and Linpan crude oil vacuum residues were investigated. The residues were separated into six fractions by use of normal pentane precipitation and liquid adsorption chromatography using alumina containing 5% water as adsorbent. The nitrogen and nickel distributions in every fraction were then observed. The removal of nickel, nitrogen and residual carbon with the liquid chromatography separation techniques are comparable with the solvent deasphalting pilot plant data. The structural parameters were calculated with modified Brown-Ladner's method on the basis of the elementary analysis, molecular weight determination and <sup>1</sup>H-NMR spectroscopy, the results obtained show that the six fractions are obviously different in their chemical compositions and structures. (Author abstract) 7 refs.

## Coloring

**077643 COLOUR AND COLOUR STABILITY ASPECTS OF PETROLEUM PRODUCTS.** Petroleum products quite often on storage show deterioration in color due to oxidation of the active hydrocarbons such as olefins, diolefins and those containing sulphur, nitrogen and oxygen. The test procedures used to measure color on various scales, color specifications of different products followed internationally and causes of color deterioration are reviewed. Refining practices followed to deal with the problems of color and color stability are discussed with the support of some experimental results. (Author abstract). 47 Refs.

Bahl, J.S. (Indian Inst of Petroleum, Dehra Dun, India); Krishna, R.; Singh, Himmat. *Indian J Technol* v 26 n 3 Mar 1988 p 120-128.

## Degradation

**077644 STRUCTURE OF HIGH-MOLECULAR-WEIGHT COMPOUNDS IN THE THERMAL DEGRADATION OF PETROLEUM RESIDUES.** The results of an investigation of the thermal-degradative transformations of the asphaltenes of petroleum residues by <sup>1</sup>H NMR spectroscopy are given. An increase in the time of thermal degradation leads to decrease in the number, in the degree of substitution, and in the length of the alkyl substituents and to an increase in the proportion of aromatic carbon atoms in the structure of the asphaltenes. The latter is determined mainly by the increase in the number of aromatic fragments. (Edited author abstract) 5 refs.

## Desulfurization

**077645 HYDRODESULPHURIZATION AND DIFUSION OF THIOPHENE ON NICKEL SULPHIDE CONTAINING CATALYSTS.** The NiS catalyst was prepared by precipitating Ni(OH)<sub>2</sub> from a Ni(NO<sub>3</sub>)<sub>2</sub> solution using ammonia solution. Adsorption-desorption isotherms were determined at -195.8°C using a static apparatus. An Arrhenius plot showing wide difference between the activities of the three catalysts, under study, for thiophene hydrodesulfurization is presented. The results show that the coprecipitated NiS/Al<sub>2</sub>O<sub>3</sub> catalyst is the most active whereas the unsupported one is the least active. Refs.

**077646 APPLICATION OF SIZE EXCLUSION CHROMATOGRAPHY WITH INDUCTIVELY COUPLED PLASMA EMISSION SPECTROMETRIC DETECTION TO RESIDUAL OIL HYDRODESULFURIZATION (HDS) AND HYDROMETALLIZATION (HDM) STUDIES.** Size exclusion chromatography with inductively coupled plasma optical emission detection (SEC-ICP) has been applied to the study of the hydroprocessing of residual oils for vanadium (HDV) and sulfur (HDS) removal. SEC-ICP and kinetic studies show that in many residual oil feeds HDV appears to follow parallel, first-order kinetics with fast and slow-reacting vanadium molecules. Application of parallel, first-order kinetics suggests that kinetics and not reactor hydrodynamics may explain deviations from ideal plug flow, first-order kinetic models observed for many hydrotreating reactions. Adequate comparison of residual oils for relative HDS activities is not accomplished by SEC alone. Desulfurization of large sulfur molecules is a combination of size reduction and removal of thiophenic sulfur. (Author abstract) 19 refs.

Distillation See PETROLEUM, CRUDE—Distillation.

## Economics

**077648 PROBLEMS AND LESSONS IN ESTIMATING SUPPLY CURVES FOR REFINED PETROLEUM PRODUCTS.** This paper describes a hybrid approach to the econometrics and process modeling of supply curves for refined petroleum products. The output from successive runs of a large-scale linear programming (LP) model of the petroleum-refining process (previously constructed for refinery analysis tasks by the U.S. Department of Energy) was used to generate a base of pseudo data from which individual short-run supply curves for each of five major refined products were then econometrically estimated.

Farmer, Richard C. (US DOE, Washington, DC, USA). *J Energy Dev* v 12 n 1 Autumn 1986 p 27-42.

## Electric Field Effects

**077649 STRUCTURE FORMATION OF MOTOR OILS IN A NONUNIFORM ELECTRIC FIELD.** The results of investigating the mechanism of structure formation of spent motor oil AS-8 in a nonuniform alternating electric field formed by electrodes having the shape of dihedral angles directed with vertices toward one another are presented. With the use of the experimental design method the optimal conditions of the most effective structure formation of the particles of the dispersed phase in an electric field were determined, which can be used when developing electrical apparatus for removing mechanical impurities, moisture, and aging products from spent motor oils. (Author abstract) 3 refs.

## Evaluation

**077650 DETERMINATION OF ACTIVE STATE OF PETROLEUM DISPERSE SYSTEMS.** The authors are reporting on an investigation of the feasibility of direct determination of the active state of an atmospheric resid on the basis of the disperse-phase particle size, for comparison with results obtained by the indirect methods that had been used previously for this purpose. As objects of investigation the authors selected atmospheric resids from Tyumen' and Tuimzy crudes, as proposed at the Novo-Ufa Petroleum Refinery. As the modifier a solvent extract obtained in treating the No. III lube cut from a mixture of these two crudes was used. The characteristics of the stocks used in this investigation are also listed. 8 refs.

## Extraction

**077651 OBTAINING VANADYL PORPHYRINS FROM ASPHALTITE OF SADKINSK DEPOSIT.** In this paper the authors are proposing a method for obtaining vanadyl porphyrins by acetone treatment of asphaltite from the Sadkinsk deposit. This particular asphaltite was selected as a starting material because of its relatively high content of vanadyl porphyrins, 766 mg/100 g, as determined by alcohol-acetone extraction. The maximum yield of vanadyl porphyrins (890 mg/100 g) was obtained by three-stage extraction: 714 mg/100 g in the first stage, 120 mg/100 g in the second, and 56 mg/100 g in the third. When ethanol was used instead of the acetone, the vanadyl porphyrin yield was 742 mg/100 g. In order to prevent loss of asphaltite and evaporation of acetone during the filtration, it is proposed that the extraction should be performed in a Soxhlet apparatus. 6 refs.

## Gravimetric Analysis

**077652 APLICACION DEL ANALISIS TERMOGRAVIMETRICO A LA DETERMINACION DE CURVAS DE FRACCIONES PESADAS DE PETROLEO.** [Application of Thermogravimetric Analysis to Determine Distillation Curves of Heavy Petroleum Fractions]. Vacuum thermogravimetric analysis (TGA) is used to determine weight loss curves of heavy petroleum fractions up to an atmospheric temperature equivalent to 800°C. These curves are compared with those obtained from gas chromatography (simulated distillation) and from those calculated by mathematical models of simulation and extrapolation of distillation curves. The results of this study show that it is possible to obtain distillation curves at temperatures higher than those attainable by conventional distillation techniques. This would allow the

determination of cut point temperatures of heavy petroleum fractions from molecular distillation. Limitations of the techniques employed are indicated and modifications and improvements are proposed. (Edited author abstract) In Spanish. 18 refs.

## Heating

**077653 EVALUATION OF BOILING PROCESS ON THE BASIS OF ELECTRICAL RESISTANCE OF PETROLEUM FRACTIONS.** A study was made of the process of petroleum product boiling and the effects of surfactant additives. The intensity of the boiling process for one particular petroleum product was rated on the basis of the change in its electrical resistance. Data indicate that a decrease in surface tension or an increase in the degree of dispersity (decrease in radius  $r$ ) will lead to increases in the number of vapor-phase nuclei and hence to increases in the electrical resistance. Thus, the character of the change in electrical resistance close to the liquid-vapor transition point when an additive is introduced can be used to judge the change in character of the phase transition due to the presence of the modifying additive. Measurements of electrical resistance can also be used to investigate the boiling process for crude oils and products. This approach offers a means for characterizing intermolecular interactions of one fraction or another in the course of the liquid-vapor phase transition, an important factor in selecting additives with the aim of increasing the yields of the desired fractions. 8 refs.

## Measurements See LIQUIDS—Measurements.

## Molecular Structure

**077655 EVALUATION OF INTERMOLECULAR INTERACTIONS IN PETROLEUM HYDROCARBONS.** Intermolecular interactions in petroleum products are responsible for structural transitions, structurization, separation of solid hydrocarbons, and loss of mobility, all of which have considerable influence on the industrial applications of the products. One method used widely to detect structural transitions is based on the temperature dependence of the electrical conductivity of the product; another method, used much less frequently, is based on the temperature dependence of viscosity. An equation for the detection of structural transitions in hydrocarbon liquids is recommended. 18 refs.

## Oxidation

**077656 PRODUCTION OF BINDER FOR PAVING MIX BY OXIDATION OF ACID-POND TAR AND ASPHALTS FROM DEASPHALTING OPERATIONS.** The rheological and service properties of binders depend on the ratio and chemical structure of the binder components, in particular the oils, resins, and asphaltenes, which create the colloidal macrostructure that is charac-

teristic for binders. In order to clarify the role and activity of individual components of the binder in chemical conversions, the authors have carried out a kinetic study of the oxidation of APT and AD, both separately and as a blend. The basic physicochemical characteristics and the group chemical composition of the APT and the AD (light grade ADL and heavy grade ADH) are given. 8 refs.

## Processing

**077660 NEW PETROLEUM WASH OIL TO RECOVER CRUDE BENZOL.** Information obtained permitted limitation of the number of products which should be investigated as solar oil substitutes. The following petroleum products were chosen for investigation as possible substitutes: (1) The deparaffinized fraction, used as a base for production of all-weather hydraulic oil; (2) Hydrogenated paraffin-naphthene fraction of the Angarsknefteorgsintez PO [Industrial Association]; (3) Distillate of the diesel fuel of the Permnefteorgsintez PO. The characteristics of the petroleum products are given. Of the oils, the deparaffinized target fraction fully meets the specifications of the crude benzol recovery process. The analysis of wash oil data are presented. A discussion is also presented of conclusions based on experimental data for the following: fractional composition, hardening temperature, separation, and, sludge formation. 6 refs.

## Quality Control

**077661 CHROMATOGRAPHIC DISTILLATION IN PETROLEUM PRODUCT QUALITY CONTROL.** The authors demonstrate the feasibility of determining the distillation curves of various petroleum products by chromatographic distillation (CD). The mixtures are separated in a capillary column or in a column packed with an inert support. Repetitive processes of vaporization and condensation take place in the flow of carrier gas. The mixtures are separated into components not according to boiling point  $t_b$  of the components, but rather according to their vapor pressure at the column exit temperature  $t_{co}$ . The results obtained confirm the possibility of universal application of the CD method; it is suitable for the analysis of various petroleum products, from gasolines to motor oils. The results also point out the possibility of combining the existing methods for the determination of distillation curve.

## Sampling See PARAFFIN WAXES—Testing.

## Spectroscopic Analysis

**077662 COMPOSITIONAL AND STRUCTURAL STUDIES OF PETROLEUM ASPHALTENES EMPLOYING SPECTROSCOPIC TECHNIQUES.** Petroleum asphaltenes of Bombay High (BH) and Gujarat Crude Mix (GCM) have been precipitated by extracting the respective residues (> 500°C) with normal heptane at room temperature. Ultimate compositions have been determined for deducing the average molecular formulas. Field ionization mass spectrometry  $^{13}C$  and  $^1H$  NMR and IR techniques have been employed to generate the structural and compositional data.  $^{13}C$  NMR provided the percentage distribution of different types of carbons and some other structural parameters. IR allowed the identification and estimation of various polar functional groups. (Edited author abstract) 24 refs.

Sarowha, S.L.S. (Indian Inst of Petroleum, Dehra-Dun, India); Singh, I.D. *Fuel* v 67 n 1 Jan 1988 p 145-146.

**077663 ROOM-TEMPERATURE PHOSPHORIMETRY TO STUDY PETROLEUM PRODUCT PERMEATION THROUGH PROTECTIVE CLOTHING MATERIALS.** A simple analytical tool based on room-temperature phosphorimetry (RTP) is developed and used for evaluating the effectiveness of protective clothing materials against permeation of organic substances containing compounds such as the polycyclic aromatic compounds. A special permeation cell is designed, which allows direct RTP measurements of the permeated products after exposure, without requiring any sample extraction procedure. Results for a variety of petroleum product-protective material combinations illustrate the usefulness of the technique. (Edited author abstract) 14 refs.

White, D.A. (Oak Ridge Natl Lab, Oak Ridge, TN, USA); Vo-Dinh, T. *Appl Spectrosc* v 42 n 2 Feb 1988 p 285-288.

## Spectrum Analysis

**077664 INTERFACIAL TENSION BEHAVIOUR AND ESR PROPERTIES OF ASPHALTENES DERIVED FROM HEAVY OIL.** Asphaltenes extracted from Lloydminster heavy oil (from Saskatchewan, Canada) were separated by sequential elution solvent chromatography (SESC) using ten different organic solvents. The fractions so obtained were dissolved in toluene and then examined for their interfacial tension (IFT) behavior against 0.1 wt.% sodium hydroxide solution. It was found that only about 40% (by weight) of the original asphaltenes contained species which were capable of lowering IFT against the alkaline solution. Multi-functional phenolic and other polar compounds were considered to be the components most likely responsible for the observed interfacial activity. Electron spin resonance measurements showed that the individual fractions contained varying

concentrations of free radicals and  $VO^{2+}$  ions. However, no direct correlation between the content of either of these two species and the interfacial tension could be detected. (Author abstract). 25 Refs.

Khulbe, Khalish C. (Univ of Ottawa, Ottawa, Ont, Can); Neale, Graham H.; Hornof, Vladimir. *Fuel Process Technol* v 19 n 1 Jul 1988 p 61-72.

**Stability** See Also PETROLEUM, CRUDE.

**077665 EFFECT OF VISBREAKING CONDITIONS ON THE STABILITY OF SOME IRAQI LONG RESIDUES.** A study has been done to investigate the change in the stability of residue during thermal process (visbreaking) at different cracking severity using flocculation ratio method. For this purpose, three long residues ( $350^{\circ}\text{C}^{+}$ ) of different crude oils were used. The obtained results were discussed as a function of reaction temperature and residence time. Moreover, the stability was correlated with the nature and chemical composition of the feedstock. We observed that the intermediate paraffinic base feedstock (type A) was more stable than the other two asphaltic base (Types B & C) when visbreaking temperature was  $460^{\circ}\text{C}$ . At higher temperatures, a sudden and large decrease in the stability of type A visbroken products was observed while only a gradual decrease in the stability of the other two products was noticed when visbreaking process was carried out at the same operating conditions. (Author abstract) 11 refs.

Savaya, Z.F. (Petroleum Research Cent, Jadriyah, Baghdad); Al-Soufi, H.H.; Al-Azawi, I.; Mohammed, H.K. *Fuel Sci Technol Int* v 6 n 3 Jun 1988 p 355-366.

**Storage** See Also DIESEL FUELS—Storage; OIL TANKS—Plastics Applications.

**077666 UNDERGROUND STORAGE TANKS: TANK OWNER'S SURVIVAL GUIDE.** Minimum requirements for new petroleum tank and pipe systems are expected to include: single-wall construction; sacrificial anode or impressed-current (electrically-charged anode) system for steel tanks and pipes, including steel pipe attached to a fiberglass tank; an overfill-containment device with a 20-gal capacity or a device to prevent overfilling; and some form of continuous leak detection for the tank and its piping. As an alternative, periodic tank and pipe tests may be conducted at intervals not exceeding 30 days. Existing steel tanks not protected against corrosion by an FRP coating, sacrificial anode or impressed-current system initially must be leak tested or frequently/continuously monitored for leaks.

Cross, Rich. *Prof Saf* v 32 n 9 Sep 1987 p 13-17.

**Structure**

**077667 EVALUATION OF COMPONENT COMPOSITION OF COMPLEX STRUCTURAL UNITS OF PETROLEUM DISPERSE SYSTEMS.** Research on the composition and properties of CSUs is greatly hindered by the lack of any methods for isolation of their components (core and solvate shell) for detailed study. The authors propose a variant of a fractionation procedure for high-molecular-weight petroleum stocks, based on stepwise extraction with a set of solvents. The objects of investigation were a vacuum resid from West Siberian crude, asphalts, and a product obtained by coking this stock. Because of the presence of a spectrum of these interactions, it is impossible to separate the CSU cores in absolutely pure form from the solvate shells enclosing the cores, hence, the fractionated products obtained by our procedure can be regarded only as concentrates of the corresponding components of the CSU. Thus, as a result of fractionation of petroleum products by the proposed methods, it is possible to recover concentrates of the solvate shell and CSU cores from petroleum disperse systems such as a petroleum resid, asphalts, coker residues, and pitches. 4 refs.

**Surface Properties**

**077668 METHOD PREDICTS SURFACE TENSION OF PETROLEUM FRACTIONS.** There is a convenient correlation for predicting the dynamic surface tension of crude oils and petroleum fractions at a specific temperature. The convenient prediction of surface tension becomes quite important wherever foaming, emulsification, droplet formation, or wetting are involved. Surface-tension data are needed, for example, when designing distillation towers, extraction units, and tower internals such as bubble caps and trays. Values computed from this equation are in good agreement with published graphs that give the values for surface tension. 2 refs.

**Viscosity**

**077669 MOLECULAR WEIGHT OF HEAVY-OIL FRACTIONS FROM VISCOSITY.** A simple equation is presented for estimating the molecular weights of heavy petroleum fractions using input parameters of kinematic viscosity  $100^{\circ}\text{F}$  and  $210^{\circ}\text{F}$ , and specific gravity at  $60^{\circ}\text{F}$ . The proposed correlation is applicable to fractions with molecular weights ranging from 200 to 800, with average errors of about 3% - less than half the error associated with previous methods. The correlation will be recommended by the American Petroleum Institute (API) in the revised Chapter 2 of its Technical Data Book - Petroleum Refining. The revision will be released in late 1987. 9 refs.

**077670 PETROLEUM HYDROGEOLOGY: A NEW BASIC IN EXPLORATION.** Petroleum hydrogeology is the science and practice of applying hydrogeological principles and techniques to petroleum exploration and basin analysis. It is based on the effects of groundwater flow on the subsurface distribution of petroleum hydrocarbons. The three basic technical arguments in favor of a hydrogeological approach to petroleum exploration are discussed. There are four general types of exploration problems to which hydrogeology may contribute, namely: (1) regional reconnaissance, (2) estimates of migrated hydrocarbon volumes, (3) location of hydrodynamic traps and stepping out from known deposits, and (4) evaluation and interpretation of surface signatures of accumulations. 46 refs.

Toth, J. (Univ of Alberta, Edmonton, Alberta, Can). *World Oil* v 205 n 3 Sep 1987 p 48-50.

**077671 POSSIBILITY OF PREDICTING ANOMALOUSLY LOW FORMATION PRESSURES FROM BUREHOLE ELECTROMETRY DATA.** Results of investigations on carbonate deposits of Upper Cretaceous at the Scythian plate of the Crimean peninsula are presented. They testify that it is possible to predict anomalously low formation pressures by the electrometry

method when drilling exploratory wells. (Translated author abstract) 2 refs. In Russian.

Orlov, A.A.; Zhuchenko, G.A. *Izv Vyssh Uchebn Zaved Neft Gaz* n 10 1986 p 3-6.

**077672 CAPILLARY PRESSURE TECHNIQUES: APPLICATION TO EXPLORATION AND DEVELOPMENT GEOLOGY.** Capillary pressure can be viewed as the pressure required to drive a fluid through a pore throat and displace the pore wetting fluid, with greater pressure being required as the pore throat becomes smaller. The size and distribution of pore throats within a host rock control its capillary pressure characteristics, which in turn control fluid behavior in the pore system. Regional capillary pressure maps of calculated values identify a north-south trend of favorable reservoir rock along the state line between Montana and North Dakota in the third porosity ('C') zone of the Ordovician Red River Formation. Oil migration and trapping can be significantly controlled by capillary pressure. Oil columns can be estimated from capillary pressure data by determining the buoyancy force of the oil floating on water and then converting from a mercury-air capillary system to an oil-water capillary system. Relative permeability data may also be calculated from capillary pressure data and can be used to estimate fractional water production at given water saturations. These and other aspects of the subject are discussed. (Edited author abstract) 25 refs.

Jennings, Jeffrey B. *AAPG Bull* v 71 n 10 Oct 1987 p 1196-1209.

**077673 INTEGRATED EXPLORATION IMPROVES WILDCAT SUCCESS, PART 2.** Integrated petroleum exploration experience to date has shown that exploration costs can total less than \$1/bbl of discovered oil reserves, and less than \$0.50/acre evaluated, when employed over large areas (several hundred sq mi). The authors present specifics on each of the exploration methods that might be included in an integrated approach. 24 refs.

Saunders, Donald F. (RECON Exploration Co, Dallas, TX, USA); Thompson, C. Keith. *World Oil* v 205 n 5 Nov 1987 p 512-405.

**077674 PROCEDURES, POSSIBILITIES AND TRENDS IN USING AEROSPACE METHODS AT THE REGIONAL AND EXPLORATION STAGES OF GEOLOGICAL PROSPECTING FOR OIL AND GAS.** Improvement of structural decoding of aerial and space photographs should be directed towards the recognition of images of regional and local structures of the productive levels of the sedimentary cover on the background of the overall landscape information. For this purpose it is necessary to carry out selection and classification of standard samples of different types of structures. Integration of multispectral, infrared and radar photographs will make it possible to expand considerably the possibilities of the remote sensing methods. One of the most important problems is improvement of the method of integrated interpretation of remote sensing photographic, geological, geophysical, hydrogeological, and geochemical data. In Russian.

Trofimov, D.M.; Polkanova, L.P. *Geol Nefti Gaza* n 5 May 1987 p 1-7.

**077675 PROSPECTING FOR STRUCTURES ON THE BASIS OF STRUCTURAL MORPHOMETRIC METHOD.** The shortcomings in the construction of morphometric and structural maps used in searching for structures are considered and the degree of their subjectivism is analyzed. With the existing methods the matching of the drilling and morphometry data is carried out by comparing available maps (secondary data) each of which contains elements of subjectivism. The proposed method eliminates it because it synthesizes drilling and morphometry data, operates with primary data, namely the absolute

depth points of the marking horizons of the geological section and morphometric surfaces. (Translated author abstract) In Russian. 2 refs.

Alekseev, V.I. *Izv Vyssh Uchebn Zaved Neft Gaz* n 5 May 1987 p 13-17.

**077676 POSSIBILITY OF UTILIZING SPECIFIC ELECTRIC RESISTANCE OF ARGILLACEOUS STRATA IN EVALUATING THE PETROLEUM POTENTIAL OF A BOREHOLE LOG.** A study of a number of oil pools of the south of the USSR represented by deposits in arenaceous-argillaceous lithological facies divided into two groups of strata - petroleum bearing and water-bearing - has shown that the specific electric resistance of the same argillaceous strata depends to a considerable extent on the productivity variations of the reservoirs that are in contact with them. Thus, electric resistance of argillaceous strata lying directly above hydrocarbon pools noticeably exceeds the specific electric resistance of the same clays lying beyond the contour of petroleum pools. This fact can be used in locating petroleum pool boundaries and capacities. 8 refs. In Russian.

**077677 EXPLORATION-STRATEGY PLANNING HELPS REDUCE RISKS AND FOCUS EXPENDITURES.** Various strategies for forecasting reserves, future discoveries, and resources have been developed over the years in an effort to quantify the probabilities of petroleum being discovered and produced for national planning purposes. While most of these calculations are not valid for individual basins or reservoirs, they can be useful in context when viewed as provincial probabilities and considered to be order of magnitude figures. Several of these extrapolations are used in this study. 15 refs.

Gerhard, Lee C. (Kansas Geological Survey, Lawrence, KS, USA); Graber, Lee A.; Brostuen, Erling A. *Oil Gas J* v 86 n 26 Jun 27 1988 4p.

**077678 PRINCIPLES OF GEOCHEMICAL PROSPECT APPRAISAL.** In most sedimentary basins, oil is expelled from source rocks between 120° and 150°C, whereas most gas and gas condensate are released between 150° and 230°C. When the initial potential of source rocks exceeds 10kg/MT, oil expulsion efficiencies are between 60 and 90 percent. Expelled oil and gas migrate as petroleum-rich phases driven by fluid potential gradients. Most flow is laterally up dip in beds with effective horizontal permeabilities greater than 1 md. In lower permeability rocks, the petroleum fluids move vertically, up or down, along the path of least resistance. Geochemical analysis of source rocks helps determine the yields and compositions of petroleum fluids expelled in the catchment area of a prospect. Evaluation of the total volume of rock through which the petroleum potentially can migrate and the mean porosity of the rocks that constitute the migration pathway allow migration losses to be assessed. (Edited author abstract). 51 Refs.

Mackenzie, Andrew S. (BP Exploration Co, London, Engl); Quigley, Tom M. *AAPG Bull* v 72 n 4 Apr 1988 p 399-415.

**077679 OIL AND GAS PLAY MAPS IN EXPLORATION AND ASSESSMENT.** Play summary maps show the superimposed boundaries of favorable areas for all key geologic controls of oil and gas occurrence - sources, migration, reservoir, trap, timing, seal, preservation, and recovery - for a genetic group of prospects or fields. These maps are invaluable for high-grading the best areas, thereby reducing exploration risks, and for quantitatively estimating hydrocarbon volume and success factors in both prospect and play assessment. Play summary maps are based on standard exploration map suites but demand a systematic integration of all the essential geologic controls, none of which can safely be ignored. (Author abstract). 21 Refs.

**077680 COOPER/EROMANGA BASINS HYDRO-CARBON POTENTIAL.** The Cooper/Eromanga basins, which occupy an area of some 1 million sq km in East Central Australia, are by far Australia's most important onshore basins. The Eromanga basin contains sediments of Jurassic age and younger, and these are underlain by Triassic and Permian sediments that were deposited in a number of smaller infrabasins of which the Cooper basin is the most important. Oil production from these basins currently comprises about 11% of Australia's total, and sales gas has been supplied to the Sydney and Adelaide markets since 1969. Condensate and liquid petroleum gas (LPG) are important by-products of this gas production. During 1985-86, Petroleum Management Associates (Australia) Pty. Ltd. (PMA) undertook a detailed technical investigation of these basins, integrating all geological, geophysical, and geochemical aspects in order to provide a complete perspective of the hydrocarbon potential for investors and explorers. Some topics discussed are these: exploration history, structure, stratigraphy, Cooper basin succession, and hydrocarbon model and exploration potential. 1 ref.

**077682 DISCOVERY AND EXPLOITATION OF NEW OILFIELDS IN THE COOPER-EROMANGA BASINS.** Since 1975 the level of petroleum exploration in the Cooper-Eromanga basins has undergone an unprecedented expansion due to the discovery and development of an increasing number of oil reservoirs, largely in the Eromanga Basin sequence. Three types of oil discovery in the Eromanga Basin sequence are evident; firstly, shallow pools above Cooper Basin gas fields; secondly, separate single-field discoveries in areas of limited exploration; and thirdly, as multifield discoveries along major structural trends. Exploitation of the Eromanga Basin oil discoveries has been made possible by a combination of rapid appraisal and development drilling and early commencement of production. (Edited author abstract) 11 refs.

**077683 PETROLEUM EXPLORATION AND DEVELOPMENTS IN QUEENSLAND DURING 1985.** Petroleum exploration in Queensland during 1985 remained at the high levels that existed during 1984. Of the 115 wells spudded, 88 were wildcat exploration wells, 24 were appraisal wells, and three were development wells. New field discoveries numbered 23, being 16 oil and 7 of

gas, the highest number ever recorded. All but two of the appraisal wells and all three development wells were successful. Queensland's petroleum reserves now stand at 66 million barrels remaining recoverable oil, 17 billion cu m gas, and 500 000 tonnes of LPG. Daily production is about 29 000 barrels of oil and condensate, about 1.2 million cu m of gas, and 97 tonnes of LPG. (Edited author abstract) 6 refs.

Randal, M.A. (Geological Survey of Queensland, Brisbane, Aust). *APEA J* v 26 pt 2 1986, 1986 APEA Conf, Adelaide, Aust, Apr 7-9 1986 p 46-62.

**077684 NEW SOUTH WALES PETROLEUM EXPLORATION AND DEVELOPMENTS 1985.** A discussion is presented of petroleum exploration and developments in New South Wales. Development activity, reserves and production, legislation and exploration policy are examined. Environmental/Aboriginal issues are also discussed. Data relative to exploration wells, development wells and seismic activity are presented in tabular form. Exploration expenditures and licenses granted are also given. 7 refs.

Etheridge, L. (NSW Government Dep of Mineral Resources, Sydney, Aust). *APEA J* v 26 pt 2 1986, 1986 APEA Conf, Adelaide, Aust, Apr 7-9 1986 p 63-69.

**077685 VICTORIA'S ROLE IN HYDROCARBON PRODUCTION AND EXPLORATION IN 1985.** In 1985, a total of sixteen exploration wells were drilled in the Gippsland Basin. Eleven of these were offshore wells, of which eight were drilled in Licence areas and three in Permit areas. Five wells were drilled in the onshore Gippsland Basin during the year. In the onshore Otway Basin, Barton Corner 1 and Fahley 1 were drilled in PEP 105 with Beach Petroleum NL as operator, and Green-slopes 1 in PEP 101 with Phoenix Oil and Gas NL as operator. In addition, with seismic surveys undertaken involving 1117 km of traverses were completed in 1985. Total production from the Gippsland fields increased during the year, and there has been a significant increase in exports.

Thompson, B.R. (Victorian Dep of Industry, Technology Resources, East Melbourne, Aust). *APEA J* v 26 pt 2 1986, 1986 APEA Conf, Adelaide, Aust, Apr 7-9 1986 p 70-73.

**077686 PETROLEUM EXPLORATION IN TASMANIA IN 1985.** 1985 saw an increase in exploration intensity in the Bass Basin, and has witnessed the Yolla oil and gas discovery well and encouraging hydrocarbon indications at the Tilana well; both wells were drilled by a consortium headed by Amoco Australia Petroleum Company. This year, 1986, has also seen a decline in offshore acreage held under permit: all current acreage is in the Bass Basin and is held by two consortia. Exploration expenditure increased sharply in 1985. To the end of 1985, 31 exploration wells had been drilled in Tasmanian waters. Of these, four have been drilled in the Otway/West Tasmanian basins, three on the Gippsland Shelf, and 24 in the Bass Basin. Geophysical surveys carried out in 1985 consisted mostly of seismic, with some marine gravity and marine magnetic. 6 refs.

Baillie, P.W. (Dep of Mines, Aust). *APEA J* v 26 pt 2 1986, 1986 APEA Conf, Adelaide, Aust, Apr 7-9 1986 p 74-76.

**077687 PETROLEUM EXPLORATION AND DEVELOPMENT IN SOUTH AUSTRALIA.** In 1985, \$103 million was spent on exploration in South Australia (51 exploration and appraisal wells plus 13 582 km of seismic). In 1986 expenditure is predicted to exceed \$100 million (52 wells, 10 000 km of seismic). These levels of exploration have been maintained since 1983 and reflect the success of the Cooper Basin Development which currently provides a gross income from the sale of petroleum products approaching \$1 billion per year, with royalties of \$50 million per year. In the period from 1976 to 1985, exploration and appraisal drilling onshore ranged

from 3 wells to 49 wells per year, with the most active year being 1984 with 62 wells. Important development projects under way in 1985 concern secondary recovery of oil in the Tirrawarra, Moorari, and Dullangari oilfields. Three significant discoveries of hydrocarbons in South Australia during 1985 were all drilled under the Accelerated Gas Program and these are described.

Frears, R. (SA Dep of Mines & Energy, Parkside, Aust). *APEA J* v 26 pt 2 1986, 1986 APEA Conf, Adelaide, Aust, Apr 7-9 1986 p 77-88.

**077688 PETROLEUM EXPLORATION, DEVELOPMENT, AND PRODUCTION IN WESTERN AUSTRALIA DURING 1985.** Phanerozoic sedimentary basins in Western Australia cover some 2.1 million sq km, divided almost equally between onshore and offshore. Of the nine principal basins, 1985 exploration activity focused on five: the Carnarvon, Canning, Perth, Bonaparte, and Browse. Western Australian production for 1985 consisted of 1.223 million kL crude oil, 2.55 billion cu m natural gas, 229 000 kL condensate, and 3057 kL LPG. Oil was produced from six fields, Barrow Island, Blina, West Terrace, Sundown, Dongara, and Mount Horner, while gas and condensate were produced from North Rankin, Dongara, Mondarra, Yardarino, and Woodada fields. Three highlights of the 1985 exploration drilling are the Saladin 1 and Harriet C1 oil discoveries offshore Carnarvon and the West Terrace 1 oil discovery onshore in the Canning Basin. Onshore the most significant oil discovery in 1985 was West Terrace 1.

Fraser, I. (Dep of Mines Western Australia, Perth, Aust). *APEA J* v 26 pt 2 1986, 1986 APEA Conf, Adelaide, Aust, Apr 7-9 1986 p 89-102.

**077689 NORTHERN TERRITORY PETROLEUM EXPLORATION AND DEVELOPMENT.** In 1985, statistics reflect accelerated development drilling in the Palm Valley and Mereenie fields, and a pause in offshore activity as key permits in the Joseph Bonaparte Gulf and Timor Sea were renewed. 1985 saw only one onshore exploration well, Waterhouse 2 in the Amadeus Basin which was unsuccessful. Re-entry and testing of the 1982 well Weaver 1 (Bonaparte Basin) yielded significant gas flows. Construction of the 1500 km gas pipeline from the Palm Valley and Mereenie fields to Darwin via Tennant Creek and Katherine commenced in August 1985. Construction of the floating production facility to be moored over the Jabiru Field has commenced, and oil production of some 2000 kL/day is scheduled to flow in mid 1986.

Le Messurier, P. (Northern Territory Dep of Mines & Energy, Darwin, Aust). *APEA J* v 26 pt 2 1986, 1986 APEA Conf, Adelaide, Aust, Apr 7-9 1986 p 103-107.

**077690 1985 APEA CONFERENCE: TECHNICAL PAPERS.** This conference proceedings contains 32 papers. Various aspects of petroleum prospecting in Australia are covered. Some of the topics discussed are: petroleum geology; petroleum reservoir engineering; geophysical applications; natural gas well logging; petrology; oil well drilling; oil well production; and automotive fuel manufacture. Other topics covered include seismic surveys; computer applications in petroleum prospecting; tectonics; exploration history; prospecting economics; and overseas recruitment of personnel. All papers are indexed and abstracted separately. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10312 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**077691 PETROLEUM PROSPECTIVITY OF THE CLARENCE-MORETON BASIN IN NEW SOUTH WALES.** The Clarence-Moreton Basin covers an area of some 28,000 km<sup>2</sup> in north-eastern New South Wales and south-eastern Queensland. The basin is relatively unexplored, with a well density in New South Wales of one per 1600 km<sup>2</sup>. Since 1980, Endeavour Resources and its

co-venturers have pursued an active exploration programme which has resulted in the recognition of significant petroleum potential in the New South Wales portion of the basin. The primary exploration targets in the Clarence-Moreton Basin sequence are Lower Jurassic sediments comprising a thick, porous and permeable sandstone unit in the Bundamba Group, and channel and point-bar sands in the Marburg Formation. (Edited author abstract) 24 refs.

Ties, P. (Webb, Jessop & Co, Melbourne, Aust); Shaw, R.D.; Geary, G.C. *APEA J* v 25 pt 1 1985, APEA Conf: Tech Pap, Perth, Aust, Mar 24-27 1985 p 15-33.

**077692 GEOLOGY AND HYDROCARBON POTENTIAL OF THE NORTH-WESTERN OFFICER BASIN.** Recent petroleum exploration in EP 186 and EP 187 in the north-western Officer Basin has greatly increased knowledge of the regional stratigraphy, structure and petroleum prospectivity of the region. This exploration programme has involved the drilling of two deep stratigraphic wells (Dragoon 1 and Hussar 1) and the acquisition of 1438 km of seismic data. Integration of regional gravity and aeromagnetic data with regional seismic and well data reveals that the Gibson Sub-basin primarily contains a Proterozoic evaporitic sequence. In contrast, the Herbert Sub-basin contains a Late Proterozoic to Cambrian clastic and carbonate sequence above the evaporites. This sequence, which was intersected in Hussar 1, is identified as the primary exploration target in the Western Officer Basin. The sequence contains excellent reservoir and seal rocks in association with mature source rocks. (Edited author abstract) 14 refs.

**077693 SOME COMMERCIAL ASPECTS OF PETROLEUM EXPLORATION AND MINING.** The petroleum industry in Australia is at the centre of a web of complex laws. In addition to the legislation under which petroleum exploration and production tenements are granted there is a multiplicity of statutes and regulations, Commonwealth and State, which have a direct bearing on the conduct of those involved in exploring for or exploiting Australia's petroleum reserves. For example, the level of participation by foreigners is governed by the Commonwealth Foreign Investment Guidelines and the Foreign Takeovers Act 1975; the Commonwealth has control over the export of petroleum under the Customs (Prohibited Exports) Regulations and domestic markets are subject to the operation of the Crude Oil Allocation Scheme. The Commonwealth continues to have the right to regulate the transfer of funds to and from Australia under the Banking (Foreign Exchange) Regulations. (Edited author abstract) 22 refs.

**077694 PERSONAL EVALUATION KEY TO TECHNICAL COMPUTING SELECTION.** The acquisition of technical computing hardware and software is an extremely personal process and a long-term commitment. Although most commercial system configurations have one of several general organizations, the individual requirements of the purchaser can have a large impact on successful implementation, even though differences between the products may seem small. In short, because each company has individual business needs, the evaluation of computing systems is not a matter of task performance, but rather one of task suitability. The end user is responsible, therefore, for choosing the most suitable system. The author presents a review of one purchaser's in-depth method for choosing the most appropriate computing environment for his company.

Shaw, Brian R. (BHP Petroleum (Americas) Inc, Houston, TX, USA). *World Oil* v 205 n 3 Sep 1987 p 39-41.

**077695 SYSTEM APPROACH TO THE PREDICTION, EXPLORATION AND PROSPECTING FOR OIL AND GAS POOLS.** A system is proposed characterizing the relationships between the conditions of formation and the regularities of distribution of oil and gas pools and the sequence of operations for predicting, exploring and prospecting them. The system shows the double role of the dynamic geosociological systems as a form of organization of the cognitive process and simultaneously as models reflecting actual reality represented in the form of geological systems. The possibility of implementing an algorithmic approach to resolve these problems is considered. The necessity of introducing informal heuristic elements into such an algorithm is demonstrated. In Russian. 6 refs.

Kerimov, V.Yu. *Izv Vyssh Uchebn Zaved Neft Gaz* n 1 1987 p 22-30.

**077696 TRENDS IN DATA ANALYSIS FOR PETROLEUM EXPLORATION AND DEVELOPMENT.** The computer world is presently locked in a race to produce the futuristic fifth generation computer, one which will simulate some parts of human intelligence. At the back of this is the current interest in expert systems and their adaptation to petroleum exploration and development. Converging hardware and software technologies, combined with industry requirements, show a definite trend to move from the emphasis on hardware and operations systems toward software and informational systems. It is not possible to predict the precise form in which this will impact petroleum industry operations but it is certain that much greater analytical power and control will rest in the hands of the interpreters enabling much higher rates of productivity and effectiveness in the location of hydrocarbon reservoirs. (Author abstract) 6 refs.

## Computer Simulation

**077697 THREE-DIMENSIONAL GRAVITY MODELING OF GULF COAST SALT DOMES.** In this article we demonstrate how gravity modeling can accurately determine the size and shape of salt domes. This is important to exploration and development of oil and gas reservoirs beneath the overhanging salt. We have shown that gravity modeling is a viable tool in the location of overhang. By the employment of this technique combined with a properly designed seismic program, using modeling, ray tracing, and correction for travel paths through the salt prior to stacking, and accurate delineation of the size and shape of the overhang can be made with a high degree of accuracy. We recommend an exploration program which uses a combination of subsurface, seismic, and gravity modeling on any prospect associated with a salt or shale dome or structure related to salt tectonics.

## Core Analysis See Also PETROLEUM GEOLOGY.

**077698 CORE ORIENTATION AND PRESENTATION OF DATA.** Orientation data such as measured from core offer many opportunities for geologic evaluation that often go overlooked or are not fully utilized. Two of the biggest difficulties appear to be that the procedures for evaluating such data are poorly described and the methods used to show such data are not adequate. The description provided of core orientation and data presentation should help in understanding what can be done and how to go about it. An example is included to show how data manipulation and the type of data presentation can alter the final interpretation. The types of data presentation discussed are equally applicable to other forms of orientation data such as from dipmeter logs.

Kirkland, James T. *Oil Gas J* v 85 n 43 Oct 26 1987 p 81-83.

**077699 NEW METHOD OF DETERMINATION OF WATER CONTENT IN SAMPLES OF OIL-SATURATED ROCKS.** In order to improve the accuracy of determination of the content of water in oil-saturated water rock samples of smaller than standard sizes, a method has been developed that is based on the property of selective permeability of polymer films by vapors of polar and nonpolar liquids. Taking into account that oil vapors are a mixture of mostly nonpolar fluids, the filtration properties of a cellophane film have been tested. The test apparatus and test procedures are described. This method is somewhat more accurate than the generally accepted extraction/distillation method. In Russian. 7 refs.

**077700 TRACKING CHANGES IN OIL EXPLORATION AND DEVELOPMENT TECHNOLOGY AND THEIR ECONOMIC IMPLICATIONS.** The objectives of this paper are to identify improvements made during the past 15 years in the technology and methods used for the exploration, development, and production of oil reserves in the U.S. Wherever possible, observations have been made with respect to the effect of these improvements on the exploitation of these reserves. Areas of research that will be of interest in the future have also been referenced. In this regard, it may be recognized that after an era in which it was important to find oil at any price to ensure supplies, the petroleum industry is now entering a period of systematic research to reduce costs in response to the new market conditions. (Author abstract) 29 refs.

**077701 INTERNATIONAL PETROLEUM INVESTMENT - WHY AUSTRALIA?** This paper presents the methodology that Conoco, a major international energy company, uses to make exploration investment decisions. This methodology includes a detailed and well coordinated analysis of the technical merits, cost environment, political/economic environment, and contract terms for every area of interest. This paper considers how each of these elements in the analysis might be a plus or a minus with regard to directing exploration funds toward Australia and shows that Australia affords an ideal mix of technical/geological merit with a workable acquisition environment and attractive economic reward. Comparisons will be made with other areas around the world. (Edited author abstract)

## Finland

**077703 HYDROCARBONS IN THE SAVIA VOLCANIC SCHIST ZONE, CENTRAL FINLAND.** Light hydrocarbon gases have been analysed from 21 samples of hydrothermally unaltered and 11 samples of hydrothermally altered metavolcanic rocks from the Savia volcanic schist zone in the southwestern part of the Proterozoic Vihanti - Pyhasalmi - Pielavesi Cu-Zn ore province, central Finland. The altered rocks are enriched in the lightest hydrocarbons (propanes and lighter) and depleted in the heavier hydrocarbons (butanes and heavier) compared with the metavolcanic rocks. The difference is clearest for methane (297.3 ppb in the altered rocks vs. 150.3 ppb in the metavolcanic rocks, becoming less marked for the heavier hydrocarbons. A pre-metamorphic hydrothermal origin related to the alteration of the volcanic rocks is the most probable reason for the difference. It is suggested, in the light of the limited data available, that a negative methane anomaly (diameter about 8 km) and positive cyclopropane and pentane anomalies (diameters about 2 km) generated by ore forming processes exist around the Savia Cu-Zn deposit. (Author abstract) 19 refs.

## Geochemistry

**077704 RELATIONSHIP BETWEEN SEDIMENT THERMAL MATURITY AND RESERVOIRED OILS WITHIN OHIO.** The objectives of this study were to evaluate the maturity of potential source units and to demonstrate the relationship between the maturity trends of the potential source units and the reservoir oils. Approximately 40 oils were analyzed for their general composition, and approximately 75 rock samples of potential Devonian source rocks for thermal maturity using standardized whole-rock vitrinite reflectance techniques. The shales from Ordovician Point Pleasant Formation were also measured for their maturity using qualitative techniques (fluorescence, thermal alteration index, and transformation ratios from Rock-Eval pyrolysis). A total of about 700 rock samples were analyzed for source quality (% TOC, Rock-Eval pyrolysis, pyrolysis-gas chromatography). 1 ref.

Gulf of Mexico See PETROLEUM GEOLOGY—Gulf of Mexico.

## Illinois

**077705 PETROLEUM FRONTIERS.** Some of the topics discussed in this paper are these: an overview of Western Illinois - the boom and after; a historical overview of drilling activity; a brief geologic history and description of units in Western Illinois; productive intervals in Western Illinois; and drilling and completion: practices and problems.

Anon. *Pet Front* v 4 n 4 1988 65p.

## Instruments

**077706 OVERVIEW OF GAS-SENSING RADAR SURVEYS THEORY, INSTRUMENTATION, SURVEYING, AND INTERPRETATION.** To investigate a possible geologic deposit of hydrocarbons, an x-band radar transmitter and its antenna direct pulses of microwave energy toward the area under investigation. The presumed petroleum gas molecules leaking out of the deposit, initially excited by the microwave, reradiate back almost instantly the absorbed energy generally at micro-

wave frequencies in a way characteristic for each kind of molecule. Neither methane nor ethane can be forced to absorb and reradiate in this fashion. However, propane has a fortuitous combination of characteristics that makes it a prime choice for seepage detection. The radar system can be mounted on a helicopter or on a truck. With helicopters, thirty to fifty square miles of flat terrain can be covered in a survey day.

## Legislation

**077707 QUEENSLAND PETROLEUM ACT - RUSTING ANACHRONISM OR WELL-OILED DISCRETION?** The current legislative framework for the exploration for petroleum in Queensland has its genesis in legislation enacted some 70 years ago. In more recent times exploration activity in Queensland has increased markedly, and there is every prospect of it being sustained at high levels for the remainder of this century. This paper reviews the history of petroleum legislation in Queensland, and outline the current provisions with respect to exploration; those provisions are then compared with industry's aims and practices, and, where any shortcomings in the legislation are identified, necessary, or appropriate, reforms are recommended. 14 refs.

## Management

**077708 EXPERT SYSTEM FOR STRATEGIC PLANNING.** An expert system program is proposed, named the Exploration Planning Assistant. The use of the expert system allows the user to manipulate and analyze huge amounts of input data. If the user organization is sophisticated, the expert system will allow modification through the addition of more refined rules and logic. If the user company is less experienced in its planning expertise, then the expert system can be built using outside experts to give the uninitiated the sophistication needed to successfully create a viable exploration plan with its associated strategies. The article discusses basic concepts of strategic planning and artificial intelligence, program decision modules, and other aspects of the subject. 2 Refs.

## Michigan

**077709 EVALUATION OF SILURIAN-NIAGARAN REEF BELT IN NORTHEASTERN MICHIGAN.** Silurian pinnacle reefs have remained the main exploration targets in the Michigan basin over the last decade. The results of exploration activities in northeastern Michigan in Cheboygan, Montmorency, and Presque Isle counties is different from the rest of the northern portion of the belt. A detailed study used the data available from the exploration activities in this area to determine the reef belt characteristics and reserves potential in northeastern Michigan and its extension into Lake Huron. The results indicated some interesting features, including the narrowing of the belt as it approaches Lake Huron. It was concluded that the different depositional environment during the Silurian Age had affected the development of the belt and the hydrocarbon accumulation in the pinnacle reefs in this part of the basin. (Edited author abstract) 13 refs.

**077710 FINDING RESERVOIR SANDS IN DEEP GULF OF MEXICO WATERS.** The distribution of sand reservoirs in the Gulf of Mexico is controlled by sea-level change, provenance (origin), rate and style of sedimentation, and structural development. An understanding of these controls is especially important in the deepwater Gulf, where sand is scarce and exploration and production costs are high. Everest Geotech uses a combination of well-log interpretation, biostratigraphy and seismic stratigraphy to recognize depositional sequences and map the distribution of potential reservoir sand. Depositional sequences related to sea level are identified by special geometric relationships of the reflectors and seismic records which have been generated by changes in sea level and the associated sediment style. 1 ref.

**077711 ATTITUDES CHANGE ABOUT N. CALIFORNIA BASINS.** Exploratory drilling in the northern California offshore basins in the mid-1960s penetrated a substantial section of oil-stained Monterey formation rocks. All the wells were abandoned because the Monterey was not considered to be a viable reservoir rock at the time. Today, oil companies are expending considerable resources preparing for upcoming lease sales in the same areas. Many companies consider the northern California basins to be one of the most prospective pioneer areas in North America.

Bachman, Steven B. (Crouch, Bachman & Associates Inc, Santa Barbara, CA, USA); Crouch, James K. *Oil Gas J* v 85 n 50 Dec 14 1987 p 55-58.

**077712 BRITISH EXPERTISE FOR DIVERLESS DEVELOPMENT OF SUBSEA OIL.** One highly promising route to low cost deep water production, as is needed, for example, in Brazil's Campos Basin project, is subsea completion - the placing of production equipment on the sea bed rather than on a conventional platform. Here the ability to go diverless has been pioneered by a number of British oil companies, notably Shell and Esso, with the Central Cormorant underwater manifold centre (UMC) in the North Sea, which was itself based on earlier work by Esso offshore Mexico. The UMC concept allows drilling and production from a centralized manifold facility normally controlled either remotely from a platform on an associated field, or from the shore. Esso is now looking at a variation of the UMC theme known as the Esso deepwater integrated production system (EDIPS) in which a sea bed manifold accepts production from template drilled wells, and also from satellite single wells nearby. Similarly Shell International has shown how to work with other countries in its own deepwater project, known as the diverless installable and maintainable oil production system (DIMOS). This article presents a review of the diverless systems.

Grange, Peter. *Mar Technol* v 18 n 4 Dec 1987 p 130-131.

**077713 C<sub>1</sub>-C<sub>8</sub> HYDROCARBONS IN SEDIMENTS FROM GUAYMAS BASIN, GULF OF CALIFORNIA TO PERU MARGIN, JAPAN TRENCH AND CALIFORNIA BORDERLANDS.** Surface seafloor sediments, hydrothermal vent samples, and Deep Sea Drilling Project sediments (Hole 481A) from the Guaymas Basin were examined for C<sub>1</sub>-C<sub>8</sub> hydrocarbons. The proportions of various classes of compounds were examined and compared to those from other geographic areas (Peru upwelling region and Japan Trench) to gain insight into the relative importance of thermal generation, migration and biodegradation. Alkene/alkane ratios of 0.1 or greater were typical of both geothermally cold sediments and also of very hydrocarbon-rich Alvin samples recovered from the seafloor. Because little or no alkene was generally

detected in buried sediments exposed to geothermal temperatures greater than 30°C, it is suggested that the alkenes are produced by biogenic processes. Similarities in compositions of branched and cyclic compounds were observed in some pairs of bitumen-rich Guaymas seafloor samples recovered from different areas, suggesting common mechanisms of light hydrocarbon generation and/or migration. (Edited author abstract). 77 Refs.

**077714 GEOCHEMICAL AND BIOLOGICAL MARKER ASSESSMENT OF DEPOSITIONAL ENVIRONMENTS USING BRAZILIAN OFFSHORE OILS.** A combined geochemical and molecular characterization of a wide selection of oils from the major Brazilian offshore basins has been undertaken. The elemental (sulfur, nickel and vanadium) and bulk (<sup>41</sup>API and <sup>813</sup>C) properties of each sample have been considered, together with its molecular composition determined using liquid and gas chromatography, and quantitative biological marker investigations using gas chromatography-mass spectrometry for alkanes. The results reveal significant differences in the chemical features of the various oils which enable them to be divided into five groups. The distinction of the groups appears to reflect differences in the depositional environment of the source rocks of the oils. Each group is correlated tentatively with source rocks laid down in a specific depositional regime, namely lacustrine freshwater, lacustrine saline water, marine evaporitic, marine carbonate or marine deltaic. Additional aspects of the subject are discussed. (Edited author abstract). 81 Refs.

Mello, M.R. (Petrobras/Cenpes/Dives, Rio de Janeiro, Brazil); Gaglianone, P.C.; Brassell, S.C.; Maxwell, J.R. *Mar Pet Geol* v 5 n 3 Aug 1988 p 205-223.

## Oklahoma

**077715 WILDCAT REOPENS DEEP ANADARKO BASIN.** Wildcat Reopens Deep Anadarko Basin. This paper reports on new exploration in the deep Anadarko basin of western Oklahoma and the Texas Panhandle. Of great significance to future exploratory work in the Anadarko basin's deep trench is the June report that Unocal Corp. spudded a geological wildcat that could set a new producing depth record for Oklahoma. Petroleum Information says that the 2-33 Bruner, SE SW NE 33-1N-25W, Beckham County, began drilling on June 14. Projected depth is 28,000 ft. Objectives will be horizons including the Hunton at 23,850 ft and the Artuckle (Cambro-Ordovician) at 28,000 ft.

McCaslin, John C. *Oil Gas J* v 86 n 30 Jul 25 1988 p 101.

## Optimization See PETROLEUM, CRUDE—Costs.

## Radioactive Methods

**077716 CARBON ISOTOPIC VARIATIONS OF KEROGEN PYROLYZATES.** A method has been developed for isotopic analysis of pyrolyzates from temperature-programmed pyrolysis of small quantities of immature to early mature kerogen concentrates. A C<sub>5</sub> pyrolyzate is collected and oxidized on-line to carbon dioxide for stable carbon isotopic measurement. Results indicate that the carbon isotopic composition of the pyrolyzate varies with final pyrolysis temperature by up to 0.7 ppt. Based on the limited pyrolyzate isotopic variation with temperature, this method is considered to have potential application to source-oil assignment problems. Correlation can be achieved via composite carbon isotopic profiling; the elegance of the method deriving from the comparison of a petroleum with the oil labile component of a candidate source kerogen assemblage. (Author abstract). 23 Refs.

Burwood, R. (Standard Oil Production Co, Irving, TX, USA); Drozd, R.J.; Halpern, H.I.; Sedivy, R.A. *Org Geochem* v 12 n 2 1988 p 195-205.

## Seismic See PETROLEUM RESERVOIR ENGINEERING.

Seismic Survey See Also OIL FIELDS—Reservoir Evaluation; PETROLEUM GEOLOGY; PETROLEUM GEOLOGY—Australia; PETROLEUM GEOLOGY—Stratigraphy.

**077717 CARBONATE POROSITY FROM S/P TRAVELTIME RATIOS.** A twenty-mile S-wave seismic line was acquired on the northeastern shelf of the Anadarko basin by the 1977-1978 Conoco P-Wave/S-Wave Group Shoot. The resolution of the S-wave section is at least as good as the resolution of a coincident P-wave section acquired in 1975. The top and bottom of a collection of Paleozoic carbonates called the Hunton group can be identified on both sets of data. P and S traveltimes and traveltime ratios delineate lateral variations in the thickness and average porosity of the Hunton. Where the pore space is saturated with liquid, a systematic increase in average porosity from less than 2 percent to about 11 percent correlates with an increase in the S/P traveltime ratio from 1.84 to 1.96. The ratio decreases to values between 1.65 and 1.80 at two places along the line, probably indicating that the pore space is partially gas-saturated at these locations. (Edited author abstract)

Robertson, James D. (ARCO Oil & Gas Co, Dallas, TX, USA). *Geophysics* v 52 n 10 Oct 1987 p 1346-1354.

**077718 INTEGRATED EXPLORATION IMPROVES WILDCAT SUCCESS.** The need to find and produce petroleum at costs that allow a reasonable profit at today's oil prices will require some drastic changes in conventional exploration philosophy. An integrated system of low-cost, direct and semidirect geochemical methods coupled with geomorphic analyses based on Landsat and/or topographic maps and NHAP (National High Altitude Photography) aerial photos is suggested as a workable solution to this problem. The savings can come from three principal sources: (1) fewer dry holes, (2) fewer unproductive leases and (3) better focusing of more expensive methods on smaller, more prospective areas. It is recommended that the Regional Reconnaissance stage include maximum practical use of available low-cost data sets, such as the NURE aerial gamma-ray spectrometer and magnetometer data, Landsat images, topographic maps, and USGS NHAP (National High Altitude Photography) coverage. 15 refs.

Saunders, Donald F. (RECON Exploration Inc, Dallas, TX, USA); Thompson, C. Keith. *World Oil* v 205 n 3 Sep 1987 p 42-46.

**077719 SACRAMENTO DELTA: NEW APPROACH TO SEISMIC EXPLORATION IN AREA OF NEAR-SURFACE PROBLEMS.** Seismic exploration of prospective areas of hydrocarbon deposits is commonly hindered by poor data quality related to near-surface problems. This article is a case history from the Sacramento delta of California, an area which locally exhibits severe near-surface problems. We review the geology of the area, discuss the nature of the near-surface problems, present the field approach developed to try to solve these problems, and show improvements gained from implementing the approach. 8 refs.

**077720 IN SEARCH OF SUBTLE FAULT TRAPS USING SEISMIC MODELING TECHNIQUES.** This article, which was designed for practical applications, deals with prospect generation around fault systems that already have established production. This is very prevalent in today's economic climate where many companies are primarily involved in close-in exploration and/or development work. The main thesis of this article is that many small faults, or obscure structures, have been passed over because they are not recognizable on older vintage seismic data. Example of synthetic seismic sections which

were generated from a geological model show that better data processing, combined with current modeling techniques, can help delineate these subtle reservoirs.

Cline, W. Michael (Amerada Hess Corp, Houston, TX, USA). *Oil Gas J* v 85 n 48 Nov 30 1987 p 56-58.

**077721 GEOTOMOGRAPHY FOR EXPLORATION OF HEAVY OIL DEPOSITS.** Seismic and electromagnetic geotomography are useful exploration techniques in heavy oil deposits. They will serve to delineate reserves and measure the progress of in-situ recovery schemes. The propagation characteristics for various Athabasca sands can be deduced from laboratory and limited field results. Such results are essential to the proper design and interpretation of exploration projects. The choice of transmission frequency in EM tomography and the choice of source design in seismic tomography are controlled by the kind of propagation expected in the project. Once these properties are converted to propagation characteristics it remains to invert the geotomographic data set to obtain structure. We suggest the use of an inversion method well-known in seismology but not widely used in industrial geotomography. The Lanczos inverse of the observation equations allows investigation of missing data, resolution of conflicting data, and a clear statement of the significance of the results. (Edited author abstract) 21 refs.

Singh, R.P. (Indian Inst of Technology, Kanpur, India); Nyland, E. *Energy Sources* v 9 n 4 1987 p 229-238.

**077722 SEISMIC EXPRESSION OF THE UPPER MORROW SANDS, WESTERN ANADARKO BASIN.** One-dimensional merged log modeling, two-dimensional log interpolation modeling, color seismic inversion processing, and seismic facies mapping techniques have been applied to the Lear and Darden fields, two Upper Morrow sand fields of the western Anadarko Basin in the Texas Panhandle. Here the Morrow sands reach an isopach thickness of 10 to 15 m at a depth of 2500 to 3000 m. These Morrow sands are within the thin-bed regime (below the tuning point) so that there is a correlation between the amplitude of the reflection and the thickness of the sand. The velocity and density contrasts of the shales and sands are sufficient to produce a good acoustic impedance contrast, making the sands detectable on seismic data with good signal-to-noise ratios. The comparison of geologic isopach mapping and geophysical seismic facies mapping shows an excellent correlation in the delineation of the Upper Morrow sands. (Edited author abstract) 2 refs.

Halverson, Jens R. (Seismic Interpretations Inc, Amarillo, TX, USA). *Geophysics* v 53 n 3 Mar 1988 p 290-303.

**077723 COMPUTER-AIDED SEISMIC INTERPRETATION SYSTEMS.** Interpretation of seismic data is very much dependent on personal experience and background knowledge of the geoscientist. However, for a few years now a new generation of computer systems has provided support in this specific area as well. Currently about half a dozen different seismic interpretation systems are marketed worldwide. Although hard- and software architecture and basic philosophy might differ somewhat, all these systems are based on one common idea: To provide support for the interpreter in his task to gain a picture, as complete and as accurate as possible, of the subsurface area he is exploring for hydrocarbons. (Author abstract)

Albert, G. (Mobil Oil AG, Celle, West Ger). *Erdoel Kohle Erdgas Petrochem* v 41 n 5 May 1988 p 190-192.

**077724 EXPERIENCE WITH THUMPER, DYNAMITE, AND VIBROSEIS SOURCES IN EP 308, THE EASTERN CANNING BASIN.** The aim of Shell's seismic survey was to acquire high resolution data in the shallow part of the section (0.3-1.0 seconds) as an aid to prospect definition. Extensive testing was carried out with Thumper, dynamite, and Vibroseis sources to determine which source would best meet this data requirement. Field processing results indicated that the Vibroseis was the best source, although special attention was needed to ensure

adequate low frequency energy was input in poor data areas. In-house processing of production and downhole Vibroseis data suggests that low frequency attenuation may still be an area for future concern. (Edited author abstract) 2 refs.

Stienstra, J.J. (Shell Co of Australia Ltd, Melbourne, Aust); Prudence, T.J.C.; Haneveld, C.J. *APEA J* v 26 pt 1 1986, 1986 APEA Conf, Adelaide, Aust, Apr 7-9 1986 p 353-362.

**077725 RECENT EXPLORATION AND HYDROCARBON POTENTIAL OF THE ROMA SHELF, QUEENSLAND.** The probability of finding additional gas reserves on the Roma Shelf within Authority to Prospect 336P and Petroleum Leases 3-13 is assessed as being very high. There is a 50 percent probability that 80 billion cubic feet (2250 million cubic metres) will be found and a 20 percent probability that 290 billion cubic feet (8170 million cubic metres) will be discovered. Recent seismic information together with geologic models developed for the Roma Shelf, Queensland have refined the settings of various plays of this important hydrocarbon province. Recent exploration has been highly successful with 67 percent of the exploration drilling resulting in new field discoveries. This success rate has stemmed from finer spaced grids of high resolution seismic which has provided accurate prospect mapping. Refinements to exploration concepts have also resulted from an integrated geological and geophysical approach. (Edited author abstract) 16 refs.

Cosgrove, J.L. (CSR, Brisbane, Aust); Mogg, W.G. *APEA J* v 25 pt 1 1985, APEA Conf: Tech Pap, Perth, Aust, Mar 24-27 1985 p 216-234.

**077726 POINT TORMENT SEISMIC SURVEY: A SEMI-PORTABLE SEISMIC OPERATION.** Point Torment, an area of low-lying tidal mudflats and adjacent coastal peninsula, was the site of a seismic survey unique to Australian geophysical exploration. This survey was conducted by Esso Australia Ltd and the area, part of EP 104, is located north of the township of Derby in Western Australia. Surface conditions in the area varied from thickly wooded grassland on the peninsula to open mudflats. Vehicle access to the mudflats was severely restricted and helicopter support was necessary to maintain the seismic operation throughout. The operation was extremely labour intensive; for example, line-cutting through mangrove areas was carried out by hand. Seismic recording was achieved using an OPSEIS® 5500 digital radio telemetry system. With this system, data is collected by portable field units. (Edited author abstract)

Angove, Ron (Esso Australia Ltd, Sydney, Aust). *APEA J* v 25 pt 1 1985, APEA Conf: Tech Pap, Perth, Aust, Mar 24-27 1985 p 248-253.

**077727 VSP CASE HISTORY, KANPA 1A, THE WESTERN OFFICER BASIN.** The Kanpa 1A Vertical Seismic Profile (VSP) was conducted for Shell by Schlumberger and incorporated variable time and depth sampling, different source offsets and recording in cased and uncased hole. Stacked VSP traces for Kanpa 1A were compared with a zero-phase seismic section and synthetic seismogram at the well. The VSP/seismic match is good and, due to poor synthetic/seismic correlation, was the basis for the final seismic/well tie. Interpretation of deep VSP data enabled the estimation of formation boundaries below the total depth of the well. (Edited author abstract) 4 refs.

Prudence, T.J.C. (Shell Development (Australia) Pty Ltd, Melbourne, Aust); Flentri, J. *APEA J* v 25 pt 1 1985, APEA Conf: Tech Pap, Perth, Aust, Mar 24-27 1985 p 254-264.

**077728 PRE-Eocene STRATIGRAPHY, STRUCTURE, AND PETROLEUM POTENTIAL OF THE BASS BASIN.** Exploration in the Bass Basin has mainly concentrated on the Eocene part of the Eastern View Coal Measures with the pre-Eocene stratigraphy hardly being tested. Structural mapping using a good quality Bureau of Mineral Resources regional seismic survey and infill

industry seismic data, in conjunction with seismic stratigraphy and well data, has generated an understanding of the structure and stratigraphy of the pre-Eocene basin, which suggests that exploration potential exists in structural and stratigraphic leads of both Paleocene and Cretaceous age. Pre-Eocene structural and stratigraphic studies of the Bass Basin thus point to reservoir and hydrocarbon source potential for possible multiple hydrocarbon exploration targets. (Edited author abstract) 22 refs.

## Siberia, USSR

**077729 COMBINED COSMOAEROGEOLOGIC AND GEOCHEMICAL INVESTIGATIONS IN NORTHERN SIBERIA.** In the course of the last 10 years, the Soviet 'Aerogeologiya' production and geological association has carried out space and aerial geological explorations in the northern regions of Siberia. As a result, some new elements of the geological structure have been detected. They are useful for solving problems of predicting potential oil and gas deposits. In the first place this concerns the rupture tectonics as well as identification of large and particularly local auticlinal structures that have become active in more recent times. Geochemical methods are based on the ideas about the filtration and diffusion mass transfer of hydrocarbon gases from a deposit to the overburden, including the ground surface and their concentration in surface waters, soils and plants. In Russian.

Bidzhiev, R.A.; Lyapina, G.G.; Rozhnova, T.A.; Vanin, A.L. *Geol Nefti Gaza* n 5 May 1987 p 13-19.

## Texas

**077730 TEST OF NATIONAL URANIUM RESOURCE EVALUATION GAMMA-RAY SPECTRAL DATA IN PETROLEUM RECONNAISSANCE.** Advances in interpretation techniques have made possible effective use of aerial high-sensitivity gamma-ray spectral data to explore for petroleum in selected environments. These data were collected by the U.S. Department of Energy during the National Uranium Resource Evaluation (NURE) program throughout the conterminous U.S. and most of Alaska between 1974 and 1981. The tests reported in this paper were carried out in three different areas of the state of Texas. It is shown that the application of high-sensitivity gamma-ray spectrometry has regional advantages and limitations, which depend on the nature, origin, moisture content, and possible shielding cover of the surface soils. If these factors are carefully considered, the NURE radiometric data offer promise as an inexpensive reconnaissance guide to help locate new onshore oil and gas prospects or possible field extensions in the East Texas Basin, the west Texas area, and similar environments. Refs.

Saunders, Donald F. (RECON Exploration, Dallas, TX, USA); Terry, Stephen A.; Thompson, C. Keith. *Geophysics* v 52 n 11 Nov 1987 p 1547-1556.

## Ukraine

**077731 EFFICACY OF GEOLOGICAL EXPLORATION FOR OIL AND GAS AT GREAT DEPTHS IN THE DNEIPER-DONETS DEPRESSION.** The maximum depth of the sedimentary cover in the Dnieper-Donets depression is 18-20 km. Sedimentary Devonian, Carboniferous, Permian and Mesozoic-Cenozoic, and possibly Paleozoic and Riphean formations are developed here. The largest quantity of explored oil and gas deposits is related to the Lower Permian and Upper Carboniferous stage. As the reserves of the top formations are being exhausted, prospecting at depths of 3500-4000 m is carried on. Commercial hydrocarbon pools have been discovered at depths below 4500 m at 33 fields; 14 deposits have productive levels at depths of more than 5000 m. The most promising areas are the Glinsko-Solokhovskii and

Talalaevsko-Rybalskii petroliferous regions, i.e. central axial and northeastern flank parts of the depression. Natural gas deposits increase with the depth. In Russian.

Zav'yalov, V.M.; Aleshko, I.F.; Kuchma, L.M.; Mel'nikchuk, T.V. *Geol Nefti Gaza* n 11 Nov 1987 p 6-9.

## United Kingdom

**077732 UNITED KINGDOM: OIL POLICY IN A CHANGING WORLD MARKET.** The United Kingdom has gone, in the space of 10 years, from producing an insignificant amount of onshore oil to being the fifth largest producer of oil worldwide, mostly from offshore fields. This turn of events has occurred for a variety of reasons, such as the fourfold oil price increases of 1973-74 and the economic recession of the 1970s, have largely fallen outside the influence and control of UK government policy. This paper shows that despite the success of the past decade the underlying failure of the UK Government to formulate an energy policy which sought to enhance the benefits of North Sea oil will, against the background of a changing world oil market, put at risk the continued exploration for and development of North Sea oil.

Humphries, M.E. (Midland Bank plc). *Q J Tech Pap Inst Pet* Oct-Dec 1986 p 57-68.

**077733 RESEARCH NECESSARY TO INCREASE THE OPPORTUNITIES FOR ECONOMIC USE OF THE UK'S RESOURCES OF ITS OCEANS AND THE EARTH BENEATH THEM.** Despite the recent collapse in oil prices, hydrocarbon deposits in the North Sea remain the United Kingdom's most commercially attractive marine resource. For this reason I have restricted the scope of this essay to research which increases the opportunities for economic use of the UK hydrocarbon resources. With oil job losses looking set to rise to as high as 32,700 by early 1988, there are more practical reasons for concentrating on this area. This essay is split into two parts. The first part addresses the title directly and lists research projects which will increase the opportunities for economic use of the UK's hydrocarbon resources. These projects have been selected by the various organizations involved in formulating offshore research strategy. The second part goes on to examine the more important factors responsible for shaping this strategy. (Edited author abstract) 28 refs.

Nowell, Graham. *Underwater Technol* v 13 n 4 Winter 1987 p 27-35.

## United States

**077734 EARLY MESOZOIC RIFT SYSTEM: HYDROCARBON FRONTIER ON THE EAST COAST.** Numerous buried Mesozoic basins are known onshore beneath the Atlantic Coastal Plain sediments from Long Island to Florida, while similar basins have been suggested offshore by aeromagnetic, gravimetric, and seismic data interpretations. However, the understanding of the economic importance of these basins has been hindered by the paucity of local and regional stratigraphic control, the lack of good, unambiguous geophysical data and, historically, a general domestic industry prejudice against nonmarine basins. Noting the changed industry attitude, a data acquisition program was commenced by Teledyne Exploration Co. to provide stratigraphically placed seismic reflection profiles across some of these basins. The article describes the program and discusses some of its recent results.

Bowman, Harold E. (Elcoex Inc, Great Falls, VA, USA); Sheppard, Richard C.; Ziegler, Daniel G. *Oil Gas J* v 85 n 41 Oct 12 1987 p 57-58, 63.

**077735 PETROLEUM EXPLORATION POTENTIAL OF THE MIDCONTINENT RIFT, U.S.A.** Assessment of the potential for petroleum of Proterozoic age in rift-related marginal and overlying axial basins indicates a possible 5 billion barrel TOC (total organic carbon content) resource. However, source volume constraints curtail that estimate to 70 million barrels of oil and 420 billion cubic feet of gas. Adequate volumes of reservoir

rock have been identified in all rift segments. The most promising horsts are fault-related clastics of Proterozoic age or more extensive basal Paleozoic sandstone that locally occurs in marginal basins along and in sheets adjacent to the rift. It is postulated that both structural and stratigraphic traps are likely to occur.

Davidson, Donald M. Jr.; Mudrey, M.G. Jr. *Geosci Wis* v 11 Sept 1986 p 63.

## Wisconsin

**077736 EXPLORATION AND LEASING.** The general public became aware of the recent interest in petroleum exploration along the Midcontinent trend in northern Wisconsin in the fall of 1983. Leasing and seismic evaluation programs have occurred along the Midcontinent trend in Kansas, Iowa, and Minnesota, as well as in Wisconsin, but the focus of this discussion is on the northwestern counties of Wisconsin from Lake Superior southwestward. Subject covered include seismic evaluation, Wisconsin leasing activity, and regulatory response to petroleum interest.

Evans, Thomas J. *Geosci Wis* v 11 Sept 1986 p 59-62.

**077737 OIL AND GAS POTENTIAL OF KEWEENAWAN MIDCONTINENT RIFT SYSTEM IN NORTHWESTERN WISCONSIN.** Extensive leasing and seismic exploration along the Keweenawan Midcontinent Rift System from Upper Michigan into Kansas centered in northwestern Wisconsin during 1983-1985. Detailed geochemical and geophysical justification for this petroleum play remains confidential, but regional geological knowledge encourages speculation. This regional geology is discussed in the paper. Keweenawan petroleum potential is heightened by inexpensive leases for large tracts of public land, relatively cheap drilling in a politically stable area, and the potential for discovering gas storage. Wisconsin, however, has high taxes and strong environmental laws, and drilling in Lake Superior would be prohibited even if a lakeside field were discovered. Exploration activity has waned due to current economics in the petroleum industry, and Amoco cancelled a 1985 wildcard in Bayfield County that would have evaluated the St. Croix Horst. (Edited author abstract)

Paull, Richard A. *Geosci Wis* v 11 Sept 1986 p 64-73.

## Accident Prevention

**077739 A COMPUTER AIDED SHUTDOWN SYSTEM ANALYSIS AND DESIGN PROCEDURE.** A procedure is developed for designing safety shutdown systems. Shutdown system configurations using different types of hardware are evaluated. The probability of the failure modes of each configuration is evaluated using failure mode analysis techniques. Unless predefined failure probability levels are met, the method evaluates iteratively various forms of part redundancy for each configuration

until the specified failure probabilities are satisfied. Then the achieved risk reduction from the use of each configuration is quantified and the corresponding total life cost is estimated. The configuration which presents the highest risk reduction and the least total life cost is selected. The proposed method is applied to the design of a shutdown system for a turbine driven compressor of an oil refinery. (Author abstract) 12 refs.

## Catalytic Cracking

**077740 PRELIMINARY HAZARDS ANALYSIS CONDUCTED ON FCCU COMPLEX.** A preliminary hazards analysis (PHA) was conducted on an actual fluid catalytic cracking unit (FCCU) complex at a refinery. The PHA was conducted to improve the FCCU's availability and profitability. The preliminary hazards analysis conducted on the FCCU had two specific objectives: to identify potential component failures that represent relatively high economic risks at the refinery, and to obtain the information necessary for performing a detailed analysis of each of the high risk areas identified. In addition, numerous recommendations for improving FCCU complex availability based on qualitative insights gained during the analysis were made. The article discusses economic risk concepts, failure modes and effects consequence of assessment, and other aspects of the subject. 7 Refs.

## Computer Applications

**077741 OPERATORS CAN USE EXPERT SYSTEMS.** Just on the horizon are expert systems that plant operators can tap to resolve problems. And such systems will be welcome indeed. This situation raises the question of 'artificial intelligence' (AI) as applied to an expert system that could answer an operator's question quickly, without needless guesswork. AI has long been the domain of science fiction writers. More recently, with the growth and availability of computers, AI has become a buzz word in the process and manufacturing industries. However, with the increasing power of computers and the availability of specialized programming methods, the paper discusses how something close to AI can be achieved.

Kerridge, A.E. (M.W. Kellogg Co, Houston, TX, USA). *Hydrocarbon Process* v 66 n 9 Sep 1987 4p between p 97 and 105.

**077742 OIL & COMPUTERS: REFINING/DESIGN.** Refiners, petrochemical processors, and engineering companies involved in process design and operation have geared their management philosophies to closely link management and operating strategies to computer technology. The result is that modern computer technology is critically linked to the way these companies do business. The important point is that companies are not using computers to simply automate existing business practices. Most indicate that in order to take full advantage of available computer technology and modern management methods, a combined integration of computer hardware and software and forward thinking management techniques is necessary. As a result, computer system departments or groups in the process companies generally serve as advisors and coordinators, very much like consultants to all of the other company departments. This places the primary responsibility for the selection and implementation of computer systems on the operating departments - essentially, the potential users of the system.

Corbett, Richard A. (Oil & Gas Journal, Tulsa, OK, USA). *Oil Gas J* v 86 n 2 Jan 11 1988 p 56-60, 62.

**077743 FCCU PROCESS CONTROL IMPROVED BY DECISION-SUPPORT COMPUTER SYSTEM PROGRAM.** Operator effectiveness, ease of troubleshooting, and control of refining processes have been improved with the installation of a decision support system (DSS) at Texas City Refining Inc. (TRC), Texas City, Tex. The DSS is used at the discretion of the operator as opposed to placing total reliance on automation to operate the refinery. Use of the DSS has enabled TCR to eliminate production of high-end-point gasoline. The system is also useful as a training device for operators. 8 refs.

**Computer Simulation** See Also MATHEMATICAL PROGRAMMING, LINEAR.

**077744 SIMULATION ANALYSIS CONSERVES ENERGY AND RESOURCES IN OLEFIN PLANT DESIGN AND OPERATION.** OSA (Operations Simulation Analysis) achieved energy and resource conservation in commercial naphtha, gas oil LPG crackers, and in process design and operations, achieving maximum profit operation at maximum operating flexibility. This report summarizes our successful story on how OSA achieved this goal in an 8 month process-improvement program. 19 refs.

Huang, Warren (Int Operations Analysis Corp, Taipei, Taiwan). *Modell Simul Control B* v 11 n 4 1987 p 55-64.

## Corrosion

**077745 GETTING THE MOST OUT OF CORROSION CONTROL.** Refineries have long recognized the cost penalties on operations of an onstream failure caused by corrosion. In 1980 Esso started to recommend the setting up of organized corrosion control programs at each of its ten European refineries. The aim of the programs was to achieve the optimum combination of reliability, safety and operating flexibility while still maintaining reasonable materials economics. The philosophy can equally be applied to chemical and other process plants.

Royse, Susan. *Process Eng (London)* v 69 n 1 Jan 1988 p 37-39.

**077746 FIRST APPLICATION OF ARTIFICIAL INTELLIGENCE FOR CORROSION CONTROL IN THE PETROLEUM INDUSTRY.** The first artificial intelligence (AI) programmed Expert Adviser for the corrosion control of a refinery process unit has been installed at the Sun Refining & Marketing Co. Yabucoa Refinery. The MOR-or-LES crude unit expert adviser is a part of the operating computer system. The Adviser provides real time analysis of process conditions and is configured to become an automatic process control system. Details regarding the problem definition, system logic, and informational responses are presented. An overview of the AI programming development and conversion to the operational computer system is discussed. (Edited author abstract)

**077747 OUTLOOK FOR ASIAN REFINERY INVESTMENTS IN THE 1990'S.** This paper focuses on a diverse group of nations in a region of Asia stretching from Pakistan in the west to Japan in the east. The region's present refining capacity of 11.5 million barrels per day (BPD) has recently operated at 74% of capacity. During the next 10 years, the economies in this region will continue to outperform the world economy. Strong economic growth combined with the energy-intensive,

developing nature of many Asian nations' economies will increase oil demand, resulting in the need for additional investments in the region's refining facilities during the 1990's. (Author abstract)

Boepple, John T. (Caltex Petroleum Corp, Dallas, TX, USA). *Energy Prog* v 7 n 3 Sep 1987 p 127-129.

**077748 REFINERY INVESTMENT AND NAVAL FUEL PRODUCTION.** Survey data and linear programming techniques have been combined to forecast probable domestic refinery configurations and the production of Navy and other fuels for the years 1990 and 1995. The forecasts suggest that Gulf and West Coast refinery investments could be used largely for support of major gasoline production. Future refinery configurations affect the availability of Navy mobility fuels. To maintain current fuel-supply levels, it appears that the military will have to pay more for Navy jet fuel relative to the prices of civilian jet fuel. The quality of Navy jet fuel is projected to be stable during the forecast period. The Navy's marine diesel fuel is forecast to be in good supply. However, the low-temperature fluidity of the fuel is expected to deteriorate. (Author abstract) 11 refs.

Hadder, G.R. (Oak Ridge Natl Lab, Oak Ridge, TN, USA); Das, S.; Davis, R.M. *Energy (Oxford)* v 13 n 1 Jan 1988 p 45-56.

## Efficiency

**077749 IMPROVING REFINERY EFFICIENCIES.** With the decline of crude prices starting two years ago and constraints in capital availability, some refiners have significantly reduced their efficiency improvement programs under the illusion that these are less critical to their operations. However, it has been the authors' experience through three recent efficiency improvement surveys that plant profitability can still be improved by 20 to 50¢/bbl (\$1.26-3.14/m<sup>3</sup>) of crude processed, even at crude prices of \$14-18/bbl (\$88-113/m<sup>3</sup>). Considering the recent competitive market for petroleum products and current indications that crude prices are rising once again, this seems a logical time to reinstate efficiency improvement programs and at least proceed with those that have little or no investment associated with them.

Lockett, W. Jr. (ENCON Associates Inc, Bernardsville, NJ, USA); Plumstead, J.A. *Chem Eng Prog* v 83 n 4 Apr 1987 p 33-36.

## Effluent Treatment

**077750 STORMWATER MANAGEMENT FOR PETROLEUM REFINERIES.** Stormwater management analysis for a petroleum refinery drainage system requires the careful consideration of all components to ensure that wastewater effluent guidelines are met during rainfall events. Refinery runoff areas can be divided into three types for stormwater management analysis: contaminated areas such as the process unit areas; potentially contaminated areas such as roadways and tank fields; and uncontaminated areas in undeveloped parts of the refinery. The management of the runoff from each area can be markedly different depending on the quality and quantity of the runoff to be dealt with. Short duration storm events are often as important as long duration events in sizing the various drainage facilities. Runoff from each area must, therefore, be analyzed carefully, with consideration given to its interaction with other drainage system components and the process wastewater flow. (Edited author abstract) 10 refs.

**077752 INVESTIGATION OF PETROLEUM REFINERY EFFLUENT TREATMENT IN AN AEROBIC FIXED-FILM BIOLOGICAL SYSTEM.** The feasibility of treating a synthetic toxic waste and a petroleum refinery effluent was evaluated using a four-stage, fixed-film aerated bioreactor with a 50 l capacity and a surface area-to-volume ratio of 72. The process performance at various waste strengths and influent flow rates was found satisfactory. Organic loading proved to be a better operational or design parameter. Treatment efficiency decreased as the loading was increased. An organic loading of 42 g COD/m<sup>2</sup>d or less is recommended to ensure good quality effluent. The reactor coped with organic and hydraulic overloads because of the good oxygen transfer capacity and the considerable quantity of attached biomass attained. Staging of the reactor was effective in damping excessive loadings. Treatment of the refinery waste in the bioreactor removed up to 80 percent of the COD and reduced the oil, sulfide and amm.N concentrations substantially, but polishing of reactor effluent using alum treatment improved effluent quality for potential reuse. (Author abstract) 12 refs.

Hamoda, M.F. (Kuwait Univ); Al-Haddad, A.A. *J Inst Water Environ Manage* v 1 n 2 Oct 1987 p 239-246.

**077753 ROLE OF GAC ACTIVITY AND PARTICLE SIZE DURING THE FLUIDIZED-BED ANAEROBIC TREATMENT OF REFINERY SOUR WATER STRIPPER BOTTOMS.** Three expanded-bed anaerobic reactors were operated in parallel on sour water stripper bottoms. Two sizes of granular activated carbon (GAC) and non-activated carbon were used in the reactors. Performance was evaluated. Results indicated that the adsorptive capacity of GAC was essential for reducing the toxicity of the wastewater, thus permitting uninhibited biological treatment. Reactor performance improved with decreasing GAC particle size and when higher loading rates of the wastewater were used. This was attributed to the increased surface available for microbial attachment and the decreased diffusional resistance to adsorption that accompany a decrease in GAC particle size. (Author abstract) 12 refs.

## Effluents

**077754 HOW TO MEET THE NEW EMISSION STANDARDS FOR REFINERIES.** This paper summarizes the options open to respond to the new and necessary emission standards. It gives an overview of the options studied. The refinery emission problem should be viewed in the context of the total European air pollution situation. Subjects covered include flue gas treatment, emission reduction combined with cogeneration, gasification of heavy oil, and desulfurization of fuel. 4 refs.

**Emissions** See HYDROFLUORIC ACID.

## Energy Conservation

**077755 SAVE BY ABSORPTION HEAT PUMPING.** Absorption heat pumping (AHP) is an absorption refrigeration system redesigned for use at temperatures entirely above ambient. Applied to fractional distillations, absorption heat pumping eliminates approximately half the reboiler steam demand by temperature elevating low-level latent heat from the tower overhead (normally rejected to the environment) and rejecting it instead to the reboiler. The mechanical vapor compressor (MVC) can also achieve this; however, the two system, AHP and MVC, differ fundamentally with respect to the practical concerns of real plant applications.

Dec 1987 p 30-31.

## Environmental Impact

**077756 DETERMINATION OF NITRATE ION CONTENT IN RECIRCULATING WATER IN PETROLEUM REFINERIES AND PETROCHEMICAL PLANTS.** Various photometric methods are used in determining small quantities of nitrates. In investigating the component composition of water in recirculating water supply systems, a rapid method is needed for nitrate determination. The authors have checked the widely used salicylate method and have found that it gives unduly low results. In this connection, a method which has been developed for determining nitrate ions using a solution of 2,6-diacetaminopyridine in concentrated  $H_2SO_4$  was found; the authors have adopted this method as the basis for the work. The relative standard deviation in determining 5-25 ml/liter of nitrate ion by this method is 0.2. The range of determinable concentrations is 0.04-2  $\mu g/ml$ . 4 refs.

**077757 PC-BASED CONTROL SYSTEM COMPLEMENTS NGL HEAT-RECOVERY PROJECT.** Valero Hydrocarbons has employed a PC-based control system to realize the energy-saving potential of a heat-recovery project at its Corpus Christi, Tex., NGL fractionator (CCF). The operation of CCF as an isobutane-butane-natural gasoline fractionation complex started in 1982. As a part of a continuing effort to optimize and improve the operations of its gas and gas-liquid processing facilities, Valero Hydrocarbons recently revamped CCF. Valero's studies revealed that the modified process, although energy efficient, could promote disturbances to the plant's heat balance with a resultant deterioration of product quality. An advanced control system would be required to compensate for disturbances. Valero selected a low-cost system which would utilize one of its surplus personal computers.

**Heat Exchangers** See Also HEAT EXCHANGERS—Scale Formation.

**077758 SPECIALTY STAINLESS STEELS INCREASE REFINERY EXCHANGER LIFE.** Practical experience using duplex (ferritic-austenitic) and high-alloyed austenitic stainless steels in various refinery heat exchangers is outlined. Although called 'specialty steels' to distinguish them from the 300 series, they are standard as to availability and fabrication properties; two most important factors for the maintenance personnel to consider. A recognition of this is the fact that today there are hundreds of heat exchangers equipped with these tubes in service in refineries around the world. 7 refs.

Berglund, G. (AB Sandvik Steel, Sandviken, Sweden); Wilhelmsson, P.H.; Martenson, C. *Hydrocarbon Process* v 67 n 1 Jan 1988 p 46-49.

## Heaters

**077759 BETTER PROCESS HEATER CONTROL.** This paper discusses some of the fundamentals of refinery and chemical plant process heater controls and gives practical data for evaluating control effectiveness. The objectives of heater control systems are to keep the operation safe and satisfy the process requirements while

maintaining maximum profit. Process heaters have a technical optimum, which is minimum cost (i.e., minimum fuel rate for the desired load). Furnaces that operate as reactors have economic optimums, which have a yield that is a trade-off between selectivity, conversion and runtime, and a cost which is proportional to the fuel flowrate. The same basic combustion control circuits are used for both types of furnaces, but the optimal control systems are different.

Stanton, B.D. (Continental Controls, Houston, TX, USA). *Hydrocarbon Process* v 66 n 7 Jul 1987 p 35-39.

**077760 SIMULACION DE CALENTADORES A FUEGO DIRECTO CILINDRICOS VERTICALES.** [Simulation of Vertical-Cylindrical Fired Heaters]. Frequently, the process equipment designer has to decide if equipment designed for specified operation conditions can be employed satisfactorily for other operating conditions, sensibly different to those originally designed for. The simulation described is for both, the radiant and convective sections. A zone method is employed to calculate the radiant heat transfer in the combustion chamber, for the heat transferred in the convective section a method proposed by C.Q. Torrijos is used. Included in this article is an algorithm to evaluate the heat transfer inside tubes. An analysis of a vertical-cylindrical fired heater is presented to illustrate the use of the methods described. (Edited author abstract) In Spanish. 8 refs.

Rangel Davalos, Humberto (Inst Mexicano del Petroleo, Mex); Parra Fernandez, Anaberti; Briones Vallejo, Victor M. *Rev Inst Mex Pet* v 19 n 2 Apr 1987 p 38-51.

**077761 ANALISIS DE FLEXIBILIDAD DE SERPENTINES DE CALENTADORES A FUEGO DIRECTO.** [Coil Flexibility Analysis of Fired Heaters]. Utilization of vertical-cylindrical fired heaters in the Campeche Bay refinery is very important due to the little plot area needed. These heaters raise the temperature of the thermal fluid that circulates inside the coil tubes. The temperature gradient, the pressure gradient and the weight causes the coil to deform. The flexibility analysis is made by a tridimensional computer program (SADAPS). (Edited author abstract) In Spanish. 2 refs.

Beltran Garcia, Jorge Luis (Inst Mexicano del Petroleo, Mex); Garcia Silva, Gustavo. *Rev Inst Mex Pet* v 19 n 2 Apr 1987 p 52-61.

**077762 COMBUSTION AIR PREHEATING FOR REFINERY HEATERS USING PLATE-TYPE HEAT EXCHANGERS.** To be justified economically, air preheating systems have to be characterized by reduced mass and volume and flexible design to allow economical integration into the heater design. Plate-type heat exchangers made of smooth plates respond well to all these requirements and gained the acceptance of the petrochemical industry worldwide. The use of air preheating is determined by economical criteria, function of energy cost and capital investment. The flow characteristics of these exchangers are presented and it is shown that the improved flow pattern results in their main advantages, i.e. reduced mass and volume while being of a heavy duty construction and with an excellent corrosion resistance.

Dinulescu, Mircea (North Atlantic Technologies (Canada) Inc, Calgary, Alberta, Can). *Energy Prog* v 8 n 2 Jun 1988 p 103-108.

## Instruments

**077763 RE-INSTRUMENTING ON A TIGHT BUDGET.** The need to upgrade control systems and instrumentation within tight budgetary constraints is a familiar theme throughout the process industries. This article outlines the steps taken by one refinery to reinstrument four plants in a four-year program. Central to the success of the approach was a planning process in which a number of important decisions were made - including decisions to standardize on one distributed control system vendor and to use a hot cutter approach to install the new control systems. (Edited author abstract) ?

Lytle, Thomas R. (Sun Refining & Marketing Co, Toledo,

OH, USA). *InTech* v 35 n 5 May 1988 p 49-51.

## Integrated Control

**077764 IMPROVING REFINERY OPERATIONS: A GOAL OF TODAY'S INSTRUMENTATION.** New microprocessor-based instruments can provide refiners with control tools capable of improving process operations. This paper discusses features and control enhancement capabilities of new instrumentation as well as its ability to provide truly centralized control. Examples illustrate integration of microprocessor-based control systems that result in highly cost-effective solutions for increasing refinery production and energy conservation. (Author abstract) 13 refs.

**Maintenance** See Also CHEMICAL PLANTS—Maintenance.

**077766 EFFECTIVE DOCUMENTATION CAN IMPROVE REVAMPS.** Revamp complexity is increased when a combination of activities must be done under a tight, fixed schedule and be integrated with a major expansion. Application of five principles leads to efficient revamp execution: 1) logical, orderly planning; 2) adequate documentation; 3) definition of exact scope before demolition or construction; 4) clear communication using standard formats; and 5) design to minimize shutdown time.

Austin, J.F. (Badger Engineers Inc, Cambridge, MA, USA); Sultan, M.S. *Hydrocarbon Process* v 66 n 11 Nov 1987 5p between p 111 and 121.

## Models

**077767 LINEAR PROGRAM OPTIMIZATION OF REFINERY SPREADSHEETS.** The advantages of representing a complex petroleum refining operation in flow diagram form showing the volume of each stream flow is evident to most engineers. With the evolution of spreadsheet refinery programming models, it became possible not only to provide such a representation but also to have it in mathematical form such that any change introduced anywhere in the refinery would reflect in all relevant stream flows, plus changes in utility use, hydrogen balance and sulfur balance. The time required for rebalancing the refinery model to show all changes on its flow diagram is about three seconds with present day microcomputers. In its simplest context, the spreadsheet model can be thought of as a complete, very fast, refinery simulator. 2 refs.

White, J.R. (Mobil Research & Development Corp, Princeton, NJ, USA). *Hydrocarbon Process* v 66 n 11 Nov 1987 p 92.

## Modernization

**077768 PROGRESS OF OCCUPATIONAL HYGIENE IN PETROLEUM REFINING INDUSTRY.** Hygienic characteristics of scientific and technical reconstruction in the petroleum refining industry is presented from 1961. Sanitary, hygienic, and socioeconomic effect of the technical reconstruction and hygienic activities have been analyzed along with the dynamic indices of workers' health status. (Author abstract) In Russian. 10 refs.

Karamova, L.M. *Gig Tr Prof Zabol* n 1 Jan 1988 p 40-44.

## Modification

**077769 GAINING AN ECONOMIC ADVANTAGE BY MODERNIZING A CRUDE UNIT.** A large Vacuum Distillation Crude Unit at Texaco's Port Arthur Plant began continuous service in the early 1970's. It was designed to refine 130k BPD of raw crude and produce simultaneous lube-oil cuts off the vacuum tower. In 1980, the unit was upgraded to 170k BPD. Texaco desired to develop an energy conservation investment program encompassing the entire unit. Near the end of 1984, a program was developed to include the following: air preheat for the four large heaters; vacuum pump installation to replace steam jet ejectors for the vacuum system; vacuum tower internal modifications; and automation and instrumentation. Using the projected fuel prices, these projects were expected to have superior economic returns.

McConnell, Marc (Texaco Refining & Marketing Inc, Port Arthur, TX, USA); Royer, Leroy Jr. *Energy Prog* v 8 n 1 Mar 1988 p 54-58.

## Nondestructive Examination

**077770 NDT EQUIPMENT AND METHODS IN PETROLEUM.** The objective of NDT (Non Destructive Testing) is to establish testing procedures, methods and routines which do not affect the process or component under test and NDT is therefore particularly suitable for the petroleum industry where many processes are continuous and where interruption of manufacturing and processing can be particularly costly. The major NDT techniques include ultrasonic testing, eddy current testing, magnetic particle inspection, x-ray inspection and visual techniques. Of these, ultrasonics is the most widely used in the petroleum industry and this is the major concern of this article. It is shown that in particular, NDT makes a significant contribution to both safety and cost control and assists in the planning of maintenance and component replacement. The application of microprocessors to conventional NDT techniques is overcoming the problems of the large amounts of data produced from petroleum and chemical plants.

## Refractory Materials

**077774 PORTABLE BURNER DRYOUTS OF REFRACTORY MUST BE PROPERLY ENGINEERED.** The drying of castable refractory linings on major refining

process units, such as fluid catalytic crackers and fluid coking units, before the mechanical completion of the units has provided practical advantages. The dryout of the lining must be carefully controlled to gradually release the water, and thereby to avoid the buildup of detrimental steam pressure within the lining material. Recently, contractors typically utilize portable, gas-fired burners for dryout service. A personal computer (PC) program was used to more effectively design the set-up of dryout equipment and address unit design parameters. The theoretical bases for these calculations are defined. Recent data from actual unit dryouts are shown and compared to predicted temperatures based on the PC calculations. These data confirm the validity of the engineering calculations, and the value of computer evaluations in the planning of portable burner dryouts. 1 ref.

## Retrofitting

**077775 RETROFITTING REFINERY AND PETROCHEMICAL PLANTS.** The author focuses on process improvements as the best way to reduce plant energy use. Despite the progress to date, there is growing evidence that these heat losses can be further reduced economically by about 20-30% in most refineries and petrochemical plants. One way to reduce the losses is to increase recovery of low-level heat by improved heat exchange, which has been the subject of most publications on plant energy conservation. A better way is to develop new process schemes that require less air/water cooling. One useful concept in developing new schemes is to concentrate on heat losses, rather than heat input, as an easier measure of proposed improvements. By an overall heat balance, eliminating a unit of energy loss is equivalent to saving a unit of heat input somewhere in the plant. 7 refs.

## Separators

**077776 DEVELOPMENT AND INTRODUCTION OF AUTOMATED SEPARATOR BLOCKS.** The common use in the USSR of single-pipeline sealed systems for simultaneous collection and transport of oil and gas instead of two-pipeline systems for separate collection and transport as also the centralization and enlargement of the oil refining points changed the conditions of separating the oil and gas mixtures. Based on the new requirements arising from a basic redesign of the oil collection,

transport, and preparation systems, the Tatar Institute of Petroleum Engineering Research developed and the 'Salavatneftemash' Production Combine organized the commercial production of standardized normal series of automated separator blocks of type UBS with preliminary gas collection.

## Shutdown See PARAFFINS—Production.

## Texas

**077777 REVAMP INCREASES SULFUR-RECOVERY CAPACITY AT CORPUS CHRISTI'S CHAMPLIN REFINING CO.** Champlin Refining Co. recently completed a revamp of the 140 long ton/day sulfur recovery plant at its 160,000-b/d Corpus Christi, Tex., refinery. The refinery needed to quickly and economically gain an incremental 15-20% in sulfur recovery capacity to boost its capability to process higher-sulfur crude oils and/or to accommodate higher conversion operation. Management decided that enrichment of the air supply to

the sulfur-recovery units with oxygen would provide the necessary capacity increase. This required replacement of two thermal reactors, replacing the existing burners, repacking the quench tower, adding a quench-water cooler, adding a quench-water circulating pump, installing an oxygen-supply system, and adding additional analysis and control equipment. The revamp resulted in an increase in sulfur recovery capacity of 30 long tons/day, in a timely and cost-effective manner, when the air supply was enriched to 30 vol % total oxygen. The modifications not only enabled the plant to increase to current capacity, but also will permit further plant debottlenecking by additional oxygen enrichment. 3 refs.

## Waste Disposal See Also INDUSTRIAL WASTES—Treatment.

**077778 HAZARDOUS-WASTE REGULATIONS SUMMARIZED FOR REFINERS.** Refiners face more stringent regulation of the treatment, storage, and disposal of hazardous wastes. Under recent regulations, a larger number of compounds have been, and are being, studied. Long-time methods of disposal, such as land farming of refinery waste, are being phased out. As a result, many refineries are changing their waste management practices. New regulations are becoming even more stringent, and they encompass a broader range of chemical constituents and processes. Continued pressure from the U.S. Congress has led to more explicit laws allowing little leeway for industry, the U.S. Environmental Protection Agency (EPA), or state agencies. A summary of the current regulations and what they mean to refiners is given. It is hoped that the summary will clarify the sometimes confusing rules, and help refiners deal with a situation that could entail major costs for the industry in the years to come.

Olschewsky, David (ERT Inc, Dallas, TX, USA); Megna, Alice. *Oil Gas J* v 86 n 1 Jan 4 1988 p 39-44.

## Waste Heat Utilization See Also TURBOMACHINERY—Waste Heat Utilization.

**077779 WASTE HEAT RECOVERY OF DURA (IRAQ) OIL REFINERY AND ALTERNATIVE CO-GENERATION ENERGY PLANT.** The first part of this paper presents a waste recovery scheme for an oil refinery energy plant. Both the wasted heat of the process return condensate and the flue gases are utilized for low temperature feedwater and fuel heating. The steam saved, both from the main steam line and turbine extraction system, was found to increase the steam and plant overall

efficiency by 18%. An alternative cogeneration energy plant is presented in the second part of this study. The proposed plant utilizes the gas turbine exhaust, in conjunction with a heat recovery boiler, to produce the process steam requirement. (Edited author abstract) 5 refs.

**077780 SHELL MIDDLE DISTILLATE SYNTHETIC PROCESS.** A description of the Shell Middle Distillate Synthesis (SMDS) process is given. In this two-stage process, which has been specifically developed for the production of middle distillates, a liquid product is obtained which typically consists of naphtha, kerosene and gas oil in the ratios 15:25:60 to 25:50:25. Starting from natural gas, a thermal efficiency for a stand-alone plant of 60% can be achieved by using shell technology for both syngas manufacture and middle distillates synthesis. Apart from the synthesis per se, special attention is paid to the production of the synthesis gas with its consequences for the overall process efficiency and the impact on the environment. (Edited author abstract)

**077781 SEVERAL APPROACHES CAN UPGRADE CALIFORNIA HEAVY CRUDES.** Because refinery processing capability on the West and Gulf Coasts may be limited for directly processing California Outer Continental Shelf (OCS) crude oil, several processing methods were studied to upgrade the OCS crude oil to a syncrude similar in properties to Alaska North Slope (ANS) crude. Processes studied include: delayed coking, Flexicoking, resid hydrotreating, and resid hydrotreating. Based on typical properties of OCS crude oils, yields from the various process configurations were compared, including alternative schemes of manufacturing hydrogen from resid vs. steam reforming of refinery off gases. Process schemes producing streams with better than target properties included bypassing untreated stocks to achieve overall syncrude specifications. The syncrude produced via these processes would be suitable for charging to West and Gulf Coast refineries with minimal refinery modification. 11 refs.

**077782 REACTION KINETIC CORRELATION EQUATION PREDICTS FLUID CATALYTIC CRACKING COKE YIELDS.** Coke yields in fluid catalytic cracking units (FCCU's) can be accurately predicted by a recently developed reaction kinetic equation. The equation has been checked against actual coke yields in both pilot and commercial FCCU's. It is well known that coke yield is important in the heat balance of fluid catalytic crackers. The amount of coke produced in the FCCU can limit the extent of the cracking reaction and, in turn, affect the primary product yields. 12 refs.

**077783 COMPARISON OF PERFORMANCE OF AN INDUSTRIAL VGO-TREATER WITH REACTOR MODEL PREDICTIONS.** A simplified reactor model can be used for predicting the performance of an industrial VGO-treater. Laboratory-scale experiments

performed on the same feed and catalyst as those in the industrial unit lead to a reactor simulation which agrees well with the data from this unit. In the laboratory experiments, it is possible to overcome the specific hydrodynamic problems of trickle-bed reactors by applying the catalyst dilution technique. Results obtained by this technique allowed the development of a reactor model which enables the user to simulate the adiabatic behavior of the industrial reactor. In this way, the significant gap between the reactor temperature in the isothermal laboratory reactor and the WABT of the industrial adiabatic reactor can be bridged. (Author abstract) 7 refs.

**077784 CONTINUOUS DEASPHALTING OF HEAVY PETROLEUM RESIDUES WITH ETHYL ACETATE.** When crude oil is vacuum distilled, about 30% of the feed remain as low value residue. Hydrocracking can upgrade this residue into valuable light hydrocarbons. The hydrocarbons could be optimized catalytically, if the residue were not to contain the metals vanadium and nickel that poison the catalyst. This contribution shows that continuous extractions of the residue with ethyl acetate yields a fraction with low metal content, while an asphaltene fraction with the remaining metal content is filtered off. (Author abstract) 15 refs.

**077785 HYDROGENATION OF SRC-II HEAVY DISTILLATE OVER Co-Mo/ALUMINA: EFFECT OF HYDROGEN SULPHIDE.** The effect of gas phase addition of H<sub>2</sub>S on the hydrogenation of SRC-II heavy distillate over reduced and/or sulphided Co/Mo/alumina was studied using a trickle bed reactor under the following conditions: temperature 400°C, pressure 9.81 MPa, LHSV 1.8 h<sup>-1</sup>, and H<sub>2</sub>/distillate feed ratio 1000 vol/vol. Hydrogenation activity, as expressed by [octahydrophenanthrene]/[phenanthrene] ratio in the product, attained its highest with the presulphided catalyst. The activity of the presulphided catalyst was not influenced by the addition of H<sub>2</sub>S. (Author abstract) 8 refs.

Yamada, Muneyoshi (Tohoku Univ, Sendai, Jpn); Obara, Toshiyuki; Shindo, Takayoshi; Yan, Jian-Wei; Amano, Akira. *Fuel* v 67 n 2 Feb 1988 p 298-299.

**077786 IMPROVING CLASP PLANT SULPHUR CAPACITY.** The COPE process (Claus Oxygen based Process Expansion), jointly developed and commercialized by Air Products and Chemicals together with Goar, Allison and Associates, has the potential of doubling the sulfur capacity of existing Claus plant which is used in over 80 percent of the world's refineries and sour gas processing plants. By oxygen enrichment, COPE adapts Claus units to process an acid gas feed with a high H<sub>2</sub>S content while reducing SO<sub>x</sub> emission to meet stricter environmental regulations. Retrofitting can offer attractive savings compared with installing new air based capacity.

Ruston, Mike (Air Products). *Pet Times* v 91 n 2216 Nov 1987 p 14.

**077787 CATALYST SELECTION FOR HYDROTREATMENT TURNAROUND.** Catalyst selection very seldom gets the attention it deserves during a hydrotreater turnaround, but proper selection of the replacement catalyst can have significant effects on hydroprocessing performance and on product values and downstream operations. Experience shows that the optimum catalyst loading for a given plant can be defined by a close working relationship between refinery operations, the refinery technical group, and the catalyst vendor. The vendor provides a performance prediction or pilot plant test indicating the expected catalyst performance at a given set of operating conditions. When looking to improve catalyst performance or activity, the following parameters should be considered: catalyst type, catalyst particle size, catalyst

shape, catalytic properties, and catalytic loading. 2 refs.

**077788 PROMOTED COMBUSTION IMPROVES FCCU FLEXIBILITY.** Well-controlled CO combustion in the regenerator of a fluid catalytic cracking unit (FCCU) can be a valuable tool for the refiner to optimize unit energy balance and conversion, and to improve the flexibility of the FCC operation. Various aspects of the combustion of coke and CO in the regenerator are influenced by variables when the unit is operated with a promoted or unpromoted catalyst system. Some topics discussed are these: coke and heat balance, nonpromoted combustion, promoted combustion, regenerator effects, temperature effects on the amount of coke burned from the regenerated catalysts (CRC), promoter content effects, after burn  $\Delta T$ , promoter type, coke selectivity and feed quality, and process variables. 7 refs.

**077789 NON-CATALYTIC HYDROCRACKING OF ASPHALTENES: 1. PRODUCT DISTRIBUTIONS.** Athabasca asphaltenes were hydrocracked (non-catalytic) at temperatures ranging from 350 to 425°C for reaction times up to 26 h in a batch autoclave reactor. Product fractions of gas, resins, oils (saturates and aromatics), coke and asphaltenes were recovered using a solvent extraction sequence. Gas products were analysed by gas chromatography. The variation of product yields with time and temperature provided insight into asphaltene structure and thermal hydrocracking reaction pathways. Primary hydrocracking products include light hydrocarbon gases, alkanes and sulphur compounds (H<sub>2</sub>S), from which the presence of corresponding moieties in the asphaltene was inferred. Primary asphaltene reactions also produce coke. (Edited author abstract) 38 refs.

**077791 REFINERY ECONOMICS AFFECTED BY FCC IMPACT ON ALKYLATION.** The fluid catalytic cracking (FCC) 'complex', including alkylation and other downstream processes, must be operated as an integrated system in order to maximize profits. Many factors have changed refining economics, including the increased demand for higher-quality unleaded gasoline. Therefore, an evaluation of the cumulative impact of the FCC operation on downstream processes must be considered to maximize the operating margin of the total complex. IONA's FCC simulation model evaluates the significant items that contribute to the impact of FCC operating condition changes. Economics and alkylation, the vapor recovery unit (VRU), polymerization, MTBE, and other processes are included in the evaluation.

McDonald, G.W.G. (IONA Ltd, Sarasota, FL, USA). *Oil Gas J* v 83 n 13 Apr 1 1985 p 111-115.

**077792 FACTORS IMPACTING REFINING INVESTMENTS FOR THE 1990S.** The author assesses the worldwide refining industry in terms of internal and external factors impacting refining in the future. The effect of crude prices on investment spending is discussed and

the demand for resid and distillates examined. Environmental concerns are outlined. Governmental impact is also measured. 18 refs.

**077793 ETUDE DES PROPRIETES RHEOLOGIQUES DES COUPES LOURDES A HAUTE TEMPERATURE ET PRESSION.** [Study of the Rheological Properties of Heavy Cuts at High Temperature and Pressure]. Processes used for the upgrading of residues and heavy oils makes use of equipment for which the optimal sizing requires understanding of the rheological properties of the hydrocarbon phase involved over a wide temperature and pressure range. The thermodynamics laboratory of the ENSM Center for Reactors and Processes has carried out the development of a viscosimeter suited for such measurements. It is based on determining the resistant torque caused by the fluid to be analyzed sheared between two coaxial cylinders with relative rotation. The viscosity range from 10 to 40,000 cP, with maximum temperatures and pressures of use being 500°C and 30 MPa. The results obtained were tested at varying temperatures and dilutions with heavy cuts from Safaniya and Boscan crudes after deasphalting or hydrovisbreaking. Reliable values were obtained for viscosity over a wide temperature range. Above 430-440°C the operating pressure of the cell increases abruptly, revealing thermal cracking of the samples, thus providing a way of studying and simulating industrial visbreaking processes. **077794 DECONTAMINATION OF PETROLEUM SLUDGES BY HOT WATER EXTRACTION.** The process of hot water extraction of tar sand was modified and adapted for removal of heavy oil from bottom tank petroleum sludges, and was submitted to a laboratory feasibility study. This process can also be utilized to clean beach sands contaminated by accidental heavy oil spills. In the case of oil contaminated sands, a single stage extraction has yielded a 99% recovery of hydrocarbons and clean sands (containing less than 0.1% of hydrocarbons) which are thus safe to be returned to the environment. In the case of petroleum bottom tank sludge, it was necessary to proceed with a double stage extraction with the addition of a wetting agent. A dosage of a  $\text{Na}_2\text{SiO}_3$  aqueous solution of 1% by weight has proven efficient, allowing an 82% recovery of hydrocarbons, with only 0.5% of hydrocarbons content in the solid residues. (Author abstract) 17 refs.

**077795 HYDROGEN-TRANSFER REACTIONS IN THE THERMAL CRACKING OF ASPHALTENES.** Experimental investigations of hydrogen-transfer reactions have been carried out with asphaltenes simulating kerogen, tetralin, and/or water as hydrogen-donor/hydrogen-transfer compounds and benzene as an inert solvent. Experiments lasted 3 h in the temperature range from 350 to 430°C in sealed gold tubes under an argon atmosphere. Our results show that tetralin is effective as a hydrogen-transfer agent and as a hydrogen-donor compound, being in kinetic competition with asphaltene hydrogen-donor moieties in this latter role. Water does not act as a hydrogen donor under the experimental conditions used but may act as a hydrogen-transfer compound in the presence of other donor molecules. (Edited author abstract) 9 refs.

**077796 ISOLATION OF ASPHALTENES USING A CONTINUOUS PRECIPITATION METHOD.** A new continuous method allows the isolation of heptane asphaltenes which are nearly identical to asphaltenes isolated by

a well-studied batch method. Samples of one-half liter of atmospheric resid can be treated using one to two liters of n-heptane, while keeping heptane/resid ratios at 40:1. Asphaltenes precipitated by a well established batch method were identical within the errors of elemental and NMR characterization methods. Small amounts of colored, heptane-soluble materials can be extracted from samples prepared by the continuous technique, but this extraction does not change the analyses of the extracted solids. (Author abstract) 3 refs.

**077797 CONTINUOUS REFORMER CATALYST REGENERATION TECHNOLOGY IMPROVED.** Since its introduction in 1971, the continuous catalyst regeneration (CCR) reforming process has been continuously pushed toward lower-pressure operation at equivalent or higher octane severity. Engineering refinement, design innovation, and desirable features discovered through start-up and operating experience have improved both the operability and profitability of the CCR reforming process. These improvements have been incorporated into revamps of existing semiregenerative reformers and into the design of a second-generation CCR process. An economic summary compares revamping and the second-generation design to semiregenerative technology.

**077798 HF ALKY UNIT OPERATIONS IMPROVED BY ON-SITE TROUBLESHOOTING TO BOOST CAPACITY, PROFIT.** When problems are encountered in the operation of hydrofluoric acid (HF) alkylation units, they can often be solved by involving the technical personnel in the process analyses and troubleshooting at the unit site. For refiners that have reduced both operating and technical staffs to cope with present economics, the troubleshooting and analyses can be done by outside consultants or technical personnel from the supplier or designer of the alkylation unit. Several cases are presented that shows how these direct field evaluations can improve a unit's capacity and profitability.

**077799 DEAROMATISING OF NAPHTHA - TECHNO - ECONOMIC ASPECTS.** The Bombay High Crude Oil of India on refining, while yielding much high octane gasoline, produces little of other needed petroleum products. One strategy is to dearomatize the crude prior to cracking. This article considers the technoeconomics of extraction of high aromatic naphtha without prior reforming operations. Experimental evidence obtained at the Indian Institute of Petroleum, Dehradun indicates such a possibility. Investigations indicate that such plants are not only commercially viable, but also financially feasible. The article summarizes investigations on the quality and quantity of naphtha available and presents process schemes along with technoeconomic considerations for solutions to predicaments.

**077802 DETERMINACION SIMULTANEA DE AZUFRE, FOSFORO Y MOLIBDENO EN CATALIZADORES FRESCOS HIDRODESULFURACION POR CROMATOGRAFIA IONICA.** [Simultaneous Determination of Sulfur, Phosphorus and Molybdenum in Hydrodesulfurization and Hydrodesulfurization Catalysts by Ion Chromatography]. A method for the simultaneous determination of sulfur, phosphorus and molybdenum in hydrometallization and hydrodesulfurization fresh catalysts is described. These elements are determined as sulfate, phosphate and molybdate by ion chromatography after sample digestion in a mixture of HF and  $\text{H}_2\text{O}_2$ . The solution obtained is adjusted to basic pH prior to injection in the chromatograph. The method was found to be free of interferences. Results obtained using real samples were compared to those of other instrumental methods showing very good agreement for concentrations ranging from 0.1 to 1.5% of  $\text{SO}_3$ , 1 to 8% of  $\text{P}_2\text{O}_5$  and 10 to 26% of  $\text{MoO}_3$ . Relative standard deviations of results were less than 4%, 1.6% and 1.5% for the sulfur, phosphorus and molybdenum determination, respectively. (Author abstract) In Spanish. 13 refs.

**077804 HYDROTREATMENT DE GAZOLES CRAQUES.** [Hydrotreatment of Cracked Gas Oils]. The hydrotreatment of various cracked gas oils was the subject of a study using NiMo/Al<sub>2</sub>O<sub>3</sub>, CoMo/Al<sub>2</sub>O<sub>3</sub> and WNi/Al<sub>2</sub>O<sub>3</sub> type catalysts for different experimental conditions. Research was done to determine the effect of pressure, temperature and type of feedstock. With an operating pressure higher than 50.6 bar, NiMo catalysts were more active for eliminating nitrogen, for aromatics saturation and for improving the cetane number. At low pressures, all the catalysts had the same activity. Strong hydrogenation conditions and NiMo type catalysts are required to improve the color, stability and cetane number of feedstocks with a high aromatics content. To obtain a stable color and a change in the cetane number (more than 2 units) for high-aromatics feedstocks, strong hydrogenation conditions and NiMo type catalysts are indispensable. (Edited author abstract) 11 refs. In French.

## Catalytic Cracking

**077806 EFFECT OF ADDED ATMOSPHERIC RESID ON PROCESS INDEXES IN CAT CRACKING OF VACUUM DISTILLATE.** No data are available on the cracking of vacuum distillate with atmospheric resids from USSR crudes. Therefore such data are obtained in order to determine the optimal ratio of components in the blend and to define the influence of the quantity of added resid on the yield and quality of the products. As feedstocks the authors selected a low-sulfur (hydrotreated) vacuum distillate and a medium-sulfur atmospheric resid, in application to a G-43-107 unit. The experiments were performed in a pilot unit at GrozNII. The experiments were performed with an equilibrium super-D microbead zeolitic catalyst. 9 refs.

**077807 INCREASE PROFITS FROM THE FCCU.** The refinery unit from which the most revenue can be generated most easily is the fluid catalytic cracking unit (FCCU). A quick review of some ideas for increasing FCCU profitability is presented. These ideas are by no means all of the methods available for increasing FCCU profitability, but they are possibilities that should be considered: increasing feed rates; improving product quality, distribution, and recovery; and reducing energy consumption.

**077808 ZSM-5 IN FCC: POTENTIAL IMPACT ON REFINERY OPERATIONS.** The use of the shape

selective zeolite ZSM-5 for octane enhancement of both FCC and TCC gasolines is described. Mobil's proprietary ZSM-5 has been evaluated in over 30 commercial cracking units. This paper discusses the twofold mechanism which explains how ZSM-5 works and presents the results from the use of ZSM-5 in EniChem Anic's FCC unit in Gela, Italy. The value of ZSM-5 in catalytic cracking is assessed. In particular, various processing schemes are discussed which show how to take maximum advantage of the changes in product distribution which occur when ZSM-5 is introduced into a cracking unit. (Edited author abstract) 12 refs.

**077809 INTENSIFICATION OF CATALYTIC CRACKING PROCESS BY ADDITION OF HEAVY CATALYTIC GASOIL.** Operation of cat cracking units yields rather large amounts of a highly aromatic product, heavy catalytic gasoil. Therefore, it has been of interest to investigate the addition of this product to cat cracker feed as a means of reducing the formation of coke. In these studies, the authors used as the feedstock a vacuum gasoil from the Moscow Petroleum Refinery, and as the activating additives a lube oil solvent extract from the Novo-Ufa Petroleum Refinery (most typical additive) and a heavy catalytic gasoil from the Moscow refinery. The authors carried out the catalytic cracking of vacuum gasoil with and without additives in a large flow-type laboratory unit with a fluidized bed of catalyst. 6 refs.

**077810 EFFECTIVENESS OF DIFFERENT PROCESS CONDITIONS IN HYDROTREATING CAT CRACKER FEED.** Cat cracker feed hydrotreating is widely practiced in industry. One of the basic indexes of the process conditions and degree of treatment is the hydrogen consumption. In this paper the authors are presenting comparative data on the effectiveness of various process conditions in hydrotreating cat cracker feed, with due regard for the hydrogen consumption. 3 refs.

**077811 STUDY OF THE LUMPING KINETIC MODEL FOR CATALYTIC CRACKING REACTION.** A description is given of the process established for a kinetic model with eleven lumps used for fluid catalytic cracking. The lumping and reaction scheme are presented for the following: heavy fuel oil (paraffin P<sub>h</sub>, naphthene N<sub>h</sub>, aromatic substituent groups A<sub>h</sub>, mono- or di-aromatic rings C<sub>Ah</sub>, polyaromatic rings PC<sub>Ah</sub>), light fuel oil (Paraffin P<sub>l</sub>, naphthene N<sub>l</sub>, aromatic substituent groups A<sub>l</sub>, aromatic rings C<sub>Al</sub>), G lump (gasoline) and C lump (C<sub>1</sub>-C<sub>4</sub>+coke). The method by which the rate constants are determined experimentally is outlined. Yields of light fuel oil, gasoline and C lump can be calculated with this model. The comparison between the results obtained in laboratory and the data of initial verification obtained from a commercial FCC unit is given. The agreement is good. (Edited author abstract) In Chinese. 18 refs.

**077812 HYDROCRACKER PERFORMANCE CORRELATED FROM ACTUAL RUNS.** Good yield correlation was developed from tests conducted on Amoco Oil Co.'s LC-Fining resid hydrocracker started nearly 2½ years ago at Amoco's Texas City, Tex., refinery. The yields were developed over a wide range of feed quality, feed rate, and operating conditions. The yields correlate well with 1,000°F+ vol% conversion over the range of 50-95% conversion. In general, yields appear

to be independent of feed rate and quality. Sulfur, Ramsbottom carbon content, and metals removal from the commercial unit tests also correlate well with 1,000°F+ conversion. 3 refs.

**Coking** See Also PETROLEUM COKE—Magnetic Field Effects.

**077813 DYNAMICS OF FORMATION OF PETROLEUM CARBON DEPOSITS ON METAL SURFACES.** In thermal contacting of petroleum pitch with a metal, carbon deposits are formed on the metal surface in the form of spiral structures that are revealed when crystallized pitch is detached from the metal. For a more detailed investigation of the dynamics of carbon deposit formation, the authors prepared model samples of petroleum pitch with different contents of carboids. The experiments were performed in a thermostated drying oven at 270°, 300°, and 330°C, with contact times of 8, 15, 30, and 45 min. Specimens of 12Kh18N10T stainless steel [similar to Type 321] were made in the form of 23-mm diameter disks with a thickness of 3 mm. 5 refs.

**077814 ADHESION IN COKING PETROLEUM RESIDS.** In the process of coking heavy petroleum resids, the reactor shell interacts with the coke, forming adhesive bonds. The adhesion is accompanied by structural, physical, and chemical conversions, and also by the evolution of volatile substances as a consequence of the high temperature of the process (up to 500°C). Because of these circumstances, the phenomena of adhesion cannot be studied by conventional methods. In this connection, we have designed and constructed a laboratory unit with a reactor, in the cylindrical body of which there are rods loosely positioned in sockets. After coking is completed and the reactor is opened, the rods are pulled out of the coke mass by means of a tensile tester. Experiments have confirmed the possibility of predicting the intensity of interaction of the coke/metal system. The shearing stress is directly related to the density of the resid and the content of asphaltene, and inversely related to the content of paraffinic hydrocarbons. 3 refs.

## Control Systems

**077815 CUT-POINT CALCULATIONS IN MODERN DCS.** Techniques utilizing distillation cut-point calculation correlations for fractionation tower optimization are presented. Their implementation and use in modern Distributed Control Systems, without the assistance of traditional peripheral devices (process computer or PC), are examined. Depending on the economic value of crude distillation products, the refiner can maximize profitably by adhering to well defined (and in some cases, seasonal) product specifications. In real-time tower control, the use of product cut-point specifications is a primary method of product quality control. 5 refs.

**Cracking** See Also CATALYSTS—Clay.

**077816 VISBREAKING WITH A REACTION CHAMBER.** Visbreaking can be defined as single-pass, light thermal cracking of petroleum resids (vacuum tars) in order to obtain boiler fuel with the required viscosity and solid point. The studies have been carried out in a pilot unit with feed to the top or bottom of the reaction chamber. The feedstocks used in this work were two samples of vacuum resid (tar) from a mixture of West Siberian and Ukhta crudes, these two tars differing in content of fractions distilling below 500°C. Both of the tars

were too high in viscosity to permit their use as commercial boiler fuel. The liquid products from the visbreaking operation were distilled into IBP-160°C, 160-350°C, and 350-500°C cuts and 500°C+residue. These cuts were back-blended to make up products with various distillation ranges. The 160°C+product (residue after distilling off the naphtha) was tested to determine its quality as Grade 100 boiler fuel. 5 refs.

**077817 SOAKER VISBREAKING OF SOME IRAQI RESIDUES.** An attempt has been made to increase the fuel oil yield of two Iraqi residues using a soaker visbreaking process. This was carried out in a continuous laboratory scale unit at a range of mild conditions, namely, 420-480°C and 43-109 sec. in the coil and 151-379 sec. in the soaker. Physical properties of the products have been characterized and reported. The fuel oils obtained under the studied conditions remained stable compared with the original feedstocks. Furthermore, data on yield and characteristics of the different distillates from the visbroken products have been obtained. There was an increase in the distillates up to 350°C (11%) for type A residue and (15%) for type B residue. (Author abstract) 5 refs.

**077818 COMBINATION OF THERMAL CRACKING WITH VACUUM DISTILLATION OF CRACKED TAR.** The traditional raw material sources (extracts from lube oil production, heavy catalytic gasoils) do not satisfy the growing demands for thermal gasoil and electrode coke. A prospective source for obtaining greater amounts of distillate feedstocks may be found in the heavy gasoil recovered by vacuum distillation of the products of thermal cracking of petroleum resids. The combination of thermal cracking with vacuum distillation of the cracked tar has made it possible to curtail the production of boiler fuel, expand the resources of feed for the production of thermal gasoil, and improve the quality of petroleum coke. The results obtained by introducing the technology of vacuum distillation of cracked tar have confirmed the correctness of the approach the authors have selected and the promise that it offers.

**Demulsification** See Also MEMBRANES.

**077819 CHEMICAL DEMULSIFICATION OF CRUDE OIL EMULSION.** There is an increasing number of crude oil fields that are now producing both crude oil and brine. The high fluid temperatures, indigenous crude oil surfactants and turbulence experienced at the wellhead chokes and valves all contribute to produce a finely dispersed emulsion of brine in crude oil. Hence most crude oils are produced in the form of emulsions. The main objective of this investigation is to improve the efficiency of the chemical resolution of the crude oil emulsion produced in the Niger Delta. (Edited author abstract) 6 refs.

**077820 VISCOSITY-TEMPERATURE PROPERTIES OF OILS IN DEWAXING RAFFINATES**

**FROM SOLVENT TREATING.** Viscosity and the variation of viscosity with temperature are important service characteristics of lube base stocks. It was shown previously that the kinematic viscosity  $\nu_{40}$  of the dewaxed oil (low-melting component) increases linearly with increasing difference between the filtration temperature and the initial crystallization of the feedstock/solvent system. Prediction of these properties on the basis of the raffinate quality and the dewaxing conditions is presented. 4 refs.

**077822 ESTIMATION OF EXERGY DIFFERENCE IN THE SEPARATING PROCESS OF PETROLEUM AND ITS DISTILLATES.** Based on the fact that the separating exergy of a complex mixture is only a function of the number of components and the distribution of their concentrations and is independent of their properties, an equation for estimating the successive separating exergy is derived through deduction and analysis. Two parameters, the distribution factor and degree of overlap of pure components are discussed and defined and are related to the separating exergy. A practical simplified equation for estimating the separating exergy of petroleum and its distillates is proposed with the purpose of efficient utilization of energy. The calculation error can be limited within the allowable range. (Author abstract) In Chinese. 3 refs.

**Economics** See PETROLEUM REFINERIES—Efficiency.

**Efficiency**

**077823 EFFICIENCY IN PETROLEUM REFINING.** In recent years substantial action has been taken within the oil refining industry to reduce their own in-house energy consumption and hence, cost. However, much of this has been achieved by technical change, including the introduction of new processes, new equipment, smaller plant with lower processing inventory, process changes and sophisticated capital intensive techniques such as process integration, involving the formal matching of heating and cooling loads and engineering the plant to suit. The bulk of this paper is concerned with the more cost-effective area of managing energy. The paper is backed up with pertinent examples and suggests that the remaining potential for achievement of operational energy usage reduction in the oil refining industry is significant. (Edited author abstract)

Roberts, Michael (PA Management Consultants). *Energy World* n 150 Aug-Sep 1987 p 13, 17.

**Energy Conservation**

**077824 RECOVER THAT LOW-LEVEL HEAT.** Direct heat integration is the best way to use heat that would otherwise be rejected. However, all heat going to cooling water, air coolers, or atmosphere that cannot be used for direct heat integration at the unit where it occurs or at a nearby unit is available for other uses remains to be recovered. This is typically process heat below 225 to 250°F. It is usually found in process streams going to condensers and coolers. Condensers offer larger quantities of heat at more constant temperature, but some large coolers with high flow rates can provide significant amounts of heat. Heat to the atmosphere via flue gas from boilers and furnaces is typically recovered by preheating combustion air, generating steam, or preheating process feed streams.

**Extraction**

**077826 CONTACT DEVICES FOR EXTRACTION TOWERS IN UNITS FOR SELECTIVE SOLVENT TREATMENT OF LUBE STOCKS.** An analysis of the operation of packed-type towers with sieve trays has shown that these towers do not provide proper conditions for coalescence of the emulsion drops after the first and successive contact stages. High values of the mass transfer coefficient can be achieved only through repeated coalescence and redispersion. On the basis of an analysis of the contact device designs that have been described here, the Ufa Branch of VNIIneftemash, in cooperation with the Novo-Ufa Petroleum Refinery, has developed an improved sieve tray design for use with the oil/phenol system. An investigation of the hydrodynamics and mass transfer in the operation of this tray has confirmed the correctness of the principles on which the design was based and has demonstrated the high efficiency of the tray. 13 refs.

**077827 FCC'S EFFECT ON REFINERY YIELDS.** For planning and optimizing an integrated refinery operation, a flowsheet system based on simulation technology has many advantages. Case studies using such a simulation system are presented to show the effect of changing FCC unit operations on the refinery scheme depicted. The studies look first at the effect of switching to an octane catalyst and then at the effect of using a deep vacuum cut point for the feed. The article concludes that the refinery-wide simulation program is easy to use because it generates its own process performance information.

Krikorian, K.V. (KBC Process Technology Ltd, Weybridge, Engl); Brice, J.C. *Hydrocarbon Process* v 66 n 9 Sep 1987 p 63-66.

**077828 NEW FCC DESIGN NOW COMMERCIAL.** In April of this year, Idemitsu Kosan Co., Ltd. brought onstream a catalytic cracking unit that incorporates new technology developed jointly by Total France and Institut Français du Pétrole. The 5,000-metric-tpd (35,000-bpd) unit is located at Idemitsu's Aichi refinery, near Tokyo. The feed is heavy resid coming from the atmospheric and vacuum crude distillation units. The investment for the unit is about 600 million French francs (\$95 million). The new process is called R2R Resid Cracking, where R2R denotes the use of one stage of reaction and two stages of catalyst regeneration. The process can convert feeds that are difficult to process, having high metals content (up to nearly 50 ppm) or high Conradson carbon (8 to 10 wt%). Features and benefits of the process are discussed.

Anon. *Hydrocarbon Process* v 66 n 9 Sep 1987 p 67.

**077829 CATALYST AGING PROCEDURE SIMULATES FCC CONDITIONS.** A hydrothermal deactivation procedure, using varied catalyst sample steaming times, has been developed to better simulate the distribution of near-fresh and moderately and severely deactivated catalyst particles in equilibrium fluid catalytic cracking (FCC) catalysts. Better simulation of the actual equilibrium catalyst results in better pilot plant simulation of actual operations, and better indications of commercial product distribution and quality. Comparison of hydrothermal deactivation procedures has shown that conventional aging of catalyst samples, that generally hydrothermally age fresh catalyst for a defined period of time, does not simulate commercial operations as well. 2 refs.

**077830 OPTIMUM FCC CONDITIONS GIVE MAXIMUM GASOLINE AND OCTANE.** The strong demand for higher octane gasoline dictates that most refineries operate their fluid catalytic crackers (FCCUs) at as high a reactor temperature as possible to produce maximum octane. Catalyst activity should also be targeted at a high level, but activity should not be high enough to overcrack the FCC gasoline to lighter  $C_3$  and  $C_4$ s. Results of laboratory studies indicate that maximum gasoline yield is achieved by maintaining an appropriate target catalyst activity at all catalyst-circulation rates.

Leuenberger, Ernest L. (Engelhard Corp, Iselin, NJ, USA). *Oil Gas J* v 86 n 12 Mar 21 1988 p 45-46.

**077831 FCC CATALYSTS CAN BE DESIGNED AND SELECTED FOR OPTIMUM PERFORMANCE.** A review of the fundamentals of FCC catalyst design, and how they relate to selection of grades that will achieve optimum performance, can simplify the selection of the optimum FCC catalyst for a particular operation and unit. Specifically, performance parameters such as zeolite type, anticipated equilibrium unit cell size, and the balance between zeolite and matrix cracking selectivity are considered. With a means to rank the selectivities of the various commercial FCC catalysts available, refiners can select catalysts that move the FCC operation nearer to process objectives, while accommodating the mechanical limitations imposed by FCC hardware. The North American refining situation is also reviewed to put the selection process into perspective with current operating practices. These practices include the increased use of octane catalysts, no appreciable increase in resid cracking, and the formulation of more catalysts for specific operations. 11 refs.

**077834 SUITABILITY OF SPENT HYDRODESULPHURISATION (HDS) CATALYST IN LOW PRESSURE DISTILLATE HYDROCRACKING - A CASE STUDY.** Due to increased demands for middle distillates, the importance of hydrocracking the heavier crude oil feedstocks is growing. Vacuum distillates from Ankleshwar and Bombay High Crudes were used as feed. The spent regenerated catalyst used, it was removed from the top bed of the gas oil HDS reactor plant after a useful life of greater than 4 years. The spent HDS catalyst, which is of negligible cost, is found to give good yields of middle distillate on processing vacuum distillates from High crudes at pressures around 80 atm. 425°C temperature and 0.5 liquid hourly space velocity. Yields of middle distillate can be increased by recycling the residue along with the fresh feed. Due to low pressure operation and the marginal cost of catalyst, the process of mild hydrocracking appears to be economically attractive. 2 refs.

**077835 NEW DEVELOPMENTS IN HYDROCRACKING: LOW PRESSURE HIGH-CONVERSION HYDROCRACKING.** Hydrogen partial pressure is a key parameter for distillate hydrocracking processes. There are two types of distillate hydrocracking processes. Mild hydrocracking is an improved vacuum gas oil hydrotreatment process with a relatively low conversion, which operates at hydrogen pressures usually less than 50 bars. Total conversion hydrocracking operates at hydrogen pressures of more than 100 bars. It is thus obvious that hydrogen pressure is a key parameter for hydrocracking performances. By looking at the different reactions taking place in the hydrocracking process, we try to explain this effect from thermodynamic and kinetic standpoints. For instance the hydroconversion of n-heptane has a negative order with respect to hydrogen pressure, when this order is positive for the conversion of a vacuum gas oil. We present pilot data showing the great influence of a first step hydrotreatment of a VGO on the second hydrocracking step. We demonstrate also the possibility of achieving very high conversion when operating at 'medium pressure' (i.e. around 70 bars) with a recently developed zeolite hydrocracking catalyst. (Author abstract) 15 refs.

## Mass Transfer

**077837 EFFECT OF ACTIVATING ADDITIVE ON PROCESS OF BOILING OF PETROLEUM FRACTIONS.** It has been established that a surface-active substance, which concentrates itself on an interface, will change the conditions of nucleation of a vapor phase in boiling and hence will change the kinetics of exchange processes between the liquid and vapor. In the work reported here, the authors investigated the influence of an activating additive - a dodecylbenzene fraction from propylene tetramers - on the boiling process in a 140-240°C straight-run cut from Kotur-Tepe crude. This particular activating additive was selected on the basis of practical considerations, as it is used in the manufacture of synthetic detergents, and the technology for its manufacture has been worked out on a commercial scale. 5 refs.

**Moisture Control** See OFFSHORE STRUCTURES—Design.

## Nitrogen Removal

**077839 HYDRODENITROGENATION CATALYSIS.** Catalytic hydrodenitrogenation (HDN) is a process in which organonitrogen compounds are removed from hydrocarbon feedstocks to produce processible, stable, and environmentally acceptable liquid fuels and lube base stocks. The purpose of this review is to give some idea of the extent to which HDN catalysis is understood. The emphasis is placed on what is known about conventional metal sulfide hydrotreating catalysts. The review begins with a brief summary of the properties of nitrogen compounds possibly pertaining to HDN catalysis. Following this is a discussion of HDN thermodynamics. The current understanding of the structure of conventional catalysts is then summarized. There follows the main body of the review, which deals with HDN kinetics and catalytic chemistry. A major portion of this part discusses the interaction between HDN and other hydroreactions

such as hydrodesulfurization and aromatics hydrogenation. The final section addresses some practical aspects of HDN, viz., catalyst development and process kinetics. 112 refs.

## Precipitation

**077840 CHARACTERIZATION OF HEAVY RESIDUA BY APPLICATION OF A MODIFIED D 2007 AND ASPHALTENE SEPARATION; EFFECT OF SOLVENTS ON PHYSICAL AND CHEMICAL PROPERTIES OF FRACTIONS DERIVED FROM HONDO 850°F RESIDUUM.** Hondo 850°F residuum was separated into saturate, aromatic, resin, and asphaltene fractions by a modified D 2007 and asphaltene separation. Two different asphaltene precipitation solvents were used - isooctane and heptane - and differences in selected physical and chemical properties of the derived fractions were compared. A small solvent dependency was seen in the concentration of S and N and the H/C. The amount of material precipitating appears to have the most dramatic effect on the elemental concentration and distribution. Included is a discussion about the significance of the differences seen in the use of the two precipitating solvents. (Edited author abstract) 24 refs.

## Waste Utilization

**077841 SEDIMENTATION OF SULFURIC ACID IN ACID TARS FROM CURRENT PRODUCTION.** One of the methods for utilization of acid tars is to burn them, producing concentrated sulfuric acid, which can then be used in treating petroleum oils. The authors investigated acid tars obtained in treating T-750 KhF-12, and I-8A oils. These tars differ from each other in their content of sulfuric acid and in the composition of the organic part. The experiments on storage of the tars were performed in separatory funnels with an electric heater; the tars were allowed to settle without stirring at temperatures of 20, 60, and 90°C. After each day of storage, the acid number was determined potentiometrically, and the amount of acid settled out was measured and expressed as a percentage. 12 refs.

**077842 MICROSCOPIC DISTRIBUTION OF WETTING AND NONWETTING PHASES IN SANDSTONES DURING IMMISCIBLE DISPLACEMENTS.** A novel technique has been developed and used to study the microscopic distribution of wetting and nonwetting phases in reservoir rocks during immiscible displacements. The underlying principle is the use of appropriate fluids, serving as the wetting and the nonwetting phases, that can be solidified in situ, one at a time, without altering to any significant extent the position and orientation of the phases acquired at capillary equilibrium conditions. After both phases are solidified, the rock matrix is etched and replaced by a resin to enhance the quality of polishing. Wettabilities of the fluid pairs were also visualized directly by this new technique. (Edited author abstract)

**077843 DEVELOPMENT OF A NEW ALUMINUM/POLYMER GEL SYSTEM FOR PERMEABILITY ADJUSTMENT.** A new method for gelling polyacrylamide with aluminum has been developed to reduce the effect of reservoir heterogeneity, resulting in improved waterflood efficiency and higher oil recovery. The method uses a soluble aluminum compound in a high-pH, nonreactive form that is mixed directly with the polymer at optimum concentrations. Polymer gelling occurs in the reservoir when reactive aluminum is generated by consumption of hydroxyl ions. Variations in gel strength and gel time are obtained by adjusting polymer and aluminate concentrations in the slug to the desired levels. This process has several advantages over the current aluminum citrate technology as well as the chromium redox bulk gel system. (Edited author abstract) 10 refs.

**077844 DETERMINATION OF BOUNDARY VALUES OF PERMEABILITY AND POROSITY OF TERRIGENOUS RESERVOIRS BY PETROPHYSICAL AND AND GEOPHYSICAL METHODS.** From the results of standard and special studies of core samples and from data of geophysical well tests, by means of statistical methods, boundary values of permeability and porosity characterizing a different degree of mobility of fluids in rocks is determined. Fluid flow takes place when rock permeability and porosity exceed some boundary values. These values may be used to identify reservoirs with a certain probability. In Russian. 7 refs.

**077845 BRAIDED STREAM RESERVOIRS.** Two types of river deposits commonly are excellent reservoirs - braided and meandering streams. Braided streams are complex networks of low-sinuosity channels that flow on alluvial plains with slopes greater than  $1/2$  to  $2'$  [0.026 to 0.034 rad]. Discharge through the channels is normally low, but during a year sporadic floods carry enormous volumes of water and sediments into the system. Lateral continuity of the pay is usually good to excellent in braided stream reservoirs and vertical continuity is fair to good. Development of production from braided stream reservoirs requires careful attention to placement of completion intervals in wells. Because the isolated shales have limited areal extent, they may not be effective in preventing coning. Thus, perforations should be placed low if a gasdrive is expected or high if waterdrive is expected. 3 refs.

Richardson, J.G. (Richardson, Sangree & Sneider); Sangree, J.B.; Sneider, R.M. *JPT J Pet Technol* v 39 n 12 Dec 1987 SPE 15782, p 1499-1500.

**077846 MEANDERING STREAM RESERVOIRS.** Braided stream deposits and meandering stream deposits commonly are excellent reservoirs. Meandering high-sinuosity channels are found on flat alluvial plains with slopes less than  $1/2$  [0.026 rad]. These rivers have wide ranges of discharges from low-water flow to flood stage. Two main processes are responsible for development of sand bodies. These are point-bar deposits left by channel migration, and oxbow-lake deposits left in loops of the river course abandoned when the stream cuts a new course during flooding. Extremely high floods spill over the banks and deposit sheets of very fine sand, silt, and clay onto the flood plain. 3 refs.

**077847 SIMULATION DES PROCESSUS DANS LES SYSTEMES A PLUSIEURS COUCHES COMPTE TENU DE L'ECHANGE LOCAL.** [Simulation of Processes in Systems with Several Layers Keeping in Mind Local Exchange]. The aim of this article is to study problems of simulating complex, nonstationary processes in systems with several layers characterized by a connection between these layers by way of local permeable zones. The influence of zones in the differential equation of the process is taken into consideration by introducing the unitary Heviside function. Results of simulation of concrete problems of liquid flow in a petroleum layer with a permeable roof are presented, as well as a comparison of these results with those of numerical calculations flowing approximate formulas obtained with Galerkin's method. In French. 7 refs.

**077848 ROCK PROPERTY CORRELATIONS FOR HYDROCARBON PRODUCING RESERVOIR SANDS OF THE NIGER DELTA.** Correlations made with petrophysical/reservoir properties from a given formation in a particular region may not yield reliable results when applied to a formation from another region even when the rock type is the same. This fact demonstrates the need for the development of empirical correlations which are unique to the hydrocarbon-producing reservoir sands of the Niger Delta. Correlation functions were sought for the petrophysical properties of the hydrocarbon-producing sands, of the Niger Delta. The relationships studied are porosity/permeability, formation resistivity factor/porosity/permeability, and porosity/water saturation. Data used for these correlations were derived from laboratory measurements on rock core samples and well logs from producing formations in the Niger Delta. Results on the above correlations appear very satisfactory. Permeability and porosity were correlated together with formation resistivity factor to produce improved results.

**077849 RESERVOIR DEVELOPMENT USING OFFSET VSP TECHNIQUES IN THE DENVER-JULESBURG BASIN.** Multioffset vertical seismic profiles (VSPs) have been used successfully to delineate and develop a Sand D field in the Denver-Julesburg basin. Sand D production in Wattenberg field was established by the Sierra Energy and Berge Exploration Well 34-3. Subsequently, three successive wells failed to find the Sand D channel. A stratigraphic model study suggested that offset VSP techniques could be used to determine the extent of the Sand D reservoir accurately and to identify potential offset drilling locations. On the basis of this study, a five-offset VSP was conducted in the discovery

well. Interpretation of the data produced an accurate map of the reservoir limits and identified two additional drilling locations. (Edited author abstract) 2 refs.

**077850 HELE-SHAW CELL STUDY OF A NEW APPROACH TO INSTABILITY THEORY IN POROUS MEDIA.** Whether a displacement is stable or unstable has a profound effect on how efficiently one fluid immiscibly displaces another within a porous medium. As a consequence it is of interest to be able to predict the boundary which separates stable displacements from those which are unstable. Recently, a new approach to stability theory has been developed which is based on the assumption that the immiscible displacement of one fluid by another can be treated as a moving boundary problem. This paper describes a number of experiments undertaken to validate the newly developed theory. Because the assumption of a sharp front between the two fluids is satisfied exactly in a Hele-Shaw cell, these preliminary experiments were undertaken in such a model. (Edited author abstract) 25 refs.

**077851 IN THE DIRECTION OF NEW RESERVOIR GEOPHYSICS.** In recent years geophysics has been brought into closer contact with reservoir interests through the implementation of high resolution seismics in the zones of interest, the development of more specialized processing, the advent of increasingly finer stratigraphic interpretations and development of three-dimensional seismics. However, the effects on the seismic signal of interface scatter as it travels through the terrain as well as alterations caused by its path in and out of the weathered layer, are some of the factors that hamper the recovery of the high resolution information that is sought. Therefore, a new direction has been taken with the development of vertical seismic profiles and more recently the appearance of new cross-hole geophysics, adapted for the reservoir. This has allowed a close up study of the reservoir. The methods of study of reservoirs by 'transparency' by the processing of trace gathers and by the study of guided wave propagation phenomena are briefly explained.

**077854 NEW APPROACH FOR CONSTRUCTING DERIVATIVE TYPE CURVES FOR WELL TEST ANALYSIS.** This work presents a new general procedure

for constructing type curves based on a new combination of dimensionless pressure and the derivative of dimensionless pressure. The procedure can be used to construct type curves for all standard problems encountered in well testing. The new type curves always have good character so that nonuniqueness problems sometimes encountered in type-curve matching are eliminated; thus, the type curves constructed by our method should improve our sometimes encountered in type-curve matching are eliminated; thus, the type curves constructed by our method should improve our ability to obtain accurate estimates of reservoir parameters by type-curve matching. The basic procedure is used to construct new type curves for wellbore storage and skin problems and for fractured wells (uniform-flux and infinite-conductivity). (Edited author abstract) 23 refs.

**077855 NOTE ON THE DURATION OF THE TRANSITIONAL PERIOD OF RESPONSES INFLUENCED BY WELLBORE STORAGE AND SKIN.** Several correlations are available for computing times at which storage effects can be considered to be negligible. The times given by these correlations are not in agreement principally because the criteria used to determine times for storage effects to become negligible are different. This paper clarifies the reasons for the differences and provides a unified treatment of the rules proposed in the literature. We show that correlations that specify the duration of the various flow periods depend on the manner in which the estimates are computed and on the tolerance used to obtain the estimate. A new correlation to determine the time for the start of the semilog straight line is presented. (Edited author abstract) 18 refs.

**077856 MODEL SELECTION FOR WELL TEST AND PRODUCTION DATA ANALYSIS.** We develop a procedure for selecting the most appropriate model from a pool of candidates. A parameter estimation algorithm is used to evaluate parameters within candidate models. Statistical measures are then used to select the most appropriate model. We demonstrate our procedure for model selection with actual well test data and production data from the Devonian shale. We show how our methodology can be used to evaluate whether certain reservoir features can be identified from measured production or pressure data. We also present a test for evaluating whether independent estimates of reservoir properties are consistent with measured pressure and production data. (Edited author abstract) 20 refs.

**077857 TWO-POINT DETERMINATIONS OF PERMEABILITY AND PV VS. NET CONFINING STRESS.** Empirical equations are presented that accurately fit permeability, PV, or porosity data vs. net confining stress. Each of these equations has four adjustable parameters. With little loss of accuracy, however, two of the coefficients can be preset. Consequently, permeability, PV, or porosity measurements need to be made at only two confining stresses - e.g., at 1,500 and 5,000 psi [10.3 and 34.5 MPa] to define the stress dependence within close tolerances completely. With the techniques described, economical measurements of these dependent properties can be made on a routine basis. The results can be used to calculate PV compressibility and to estimate productivity declines resulting from permeability reduction as deep, high-pressure reservoirs are drawn down. (Author abstract) 36 refs.

**077861 INFLUENCE OF SAMPLE SIZE AND PERMEABILITY DISTRIBUTION IN HETEROGENEITY MEASURES.** This study evaluates the influence of sample size on the Dykstra-Parsons and Lorenz measures of heterogeneity. Because either coefficient is determined for a reservoir from a finite number of data, only an estimate is made of the true coefficient. We show that, on average, the estimate is less than the true value. We give the relationship between estimate error and number of samples and show how significant errors may arise when too few data are used. The influence of the permeability distribution on heterogeneity measures is also studied. We show that a variety of distributions exhibiting different reservoir performance can have the same Dykstra-Parsons coefficient. (Edited author abstract) 18 refs.

**077862 EOS PREDICTIONS OF COMPRESSIBILITY AND PHASE BEHAVIOR IN SYSTEMS CONTAINING WATER, HYDROCARBONS, AND CO<sub>2</sub>.** Two cubic equations of state (EOS) have been adopted to compute multicomponent two-phase compressibility, CO<sub>2</sub>/water and hydrocarbon/water phase behavior, and gas- and liquid-phase densities. The equations used are the Schmidt-Wenzel (SW) EOS and the Peng-Robinson (PR) EOS. While these cubic equations have the same form, the SW is reported to be more accurate for predicting hydrocarbon gas- and liquid-phase densities. Density predictions are compared with experimental data to confirm the superiority of the SW EOS. The use of EOS

to predict equilibrium phase compositions of water/hydrocarbon and water/CO<sub>2</sub> systems is discussed. For the water/hydrocarbon systems, the aqueous-phase interaction coefficient between water and the dissolved component shows a strong temperature dependency, while in the gas phases, a constant value of interaction coefficient is adequate. (Edited author abstract) 40 refs.

**077863 SOME INVARIANT SOLUTIONS TO TWO-PHASE FLUID DISPLACEMENT PROBLEMS INCLUDING CAPILLARY EFFECT.** Analytical investigation of the two-phase displacement problem that considers capillary force is one of the most important and difficult problems in the theory of fluid flow through porous media. This paper presents some invariant solutions on the subject, including a self-similar solution for the axisymmetric case, a self-similar solution in a linear, isoclinic reservoir that considers the effects of gravity and capillary forces simultaneously, and a progressive wave solution corresponding to a stabilized zone of saturation distribution. The relations and differences among (1) a model that completely includes capillary effect, (2) a model that considers capillary action partially and implicitly (the Buckley-Leverett model), and (3) a model that completely ignores capillary effect are indicated and discussed. (Author abstract) 14 refs.

**077864 IMPORTANCIA DE LA DIFUSION EN EL DESPLAZAMIENTO DE FLUIDOS EN YACIMIENTOS PETROLIFEROS.** [Importance of Diffusion in Fluid Displacement Within Oil Reservoirs]. Molecules of all fluids have random movements of the Brownian type. Due to these movements, a fluid can be diffused into another, when there is miscibility between them. During the exploitation stage of reservoirs, the diffusion phenomenon generally is not taken into account. In this paper, a study is made of this subject, and it is concluded that diffusion is an important phenomenon for fluid displacement within reservoirs. Consequently, a sound knowledge of diffusion properties is necessary for improving oil recovery. (Edited author abstract) In Spanish. 7 refs.

Perez Rosales, Candelario (Inst Mexicano del Petroleo, Mex). *Rev Inst Mex Pet* v 19 n 2 Apr 1987 p 12-17.

**077865 SLUG-TEST ANALYSIS IN DOUBLE-POROSITY RESERVOIRS.** The pressure response of a double-porosity reservoir to a slug test in a fully penetrating well with wellbore storage and skin is presented. Pseudosteady-state matrix flow and transient matrix flow with and without matrix skin are considered. Three kinds of type curves are discussed: early-time log-log, intermediate-time semilog, and late-time log-log. Pressure distribution around the active well and the prospects of interference slug testing are considered. The early-time response of the slug test depends on the presence of wellbore skin; hence, two kinds of early-time type curves are presented. When the active well has wellbore skin, the early-time correlating parameter is the product of the skin and the dimensionless storage, resulting in a new log-log type curve. When wellbore skin is not present, the early-time response is proportional to the square root of time with dimensionless storage as the correlating parameter. (Edited author abstract). 31 refs.

**077866 PREDICTION OF ABRUPT RESERVOIR COMPACTION AND SURFACE SUBSIDENCE CAUSED BY PORE COLLAPSE IN CARBONATES.** A new procedure has been developed to predict the abrupt in-situ compaction and the associated surface subsidence above high-porosity carbonate fields that show pore collapse. The approach is based on an extensive laboratory

compaction study in which the effects of carbonate type, porosity, core preparation, pore saturant, horizontal/vertical stress ratio, and loading rate on pore-collapse behavior were investigated. For a number of carbonate types, a trendline was established that describes the relationship between the porosity after collapse and the vertical effective stress. This trendline concept, in combination with existing subsidence models, enables reservoir compaction and surface subsidence to be predicted on the basis of wireline porosity logs. Static and dynamic elastic constants were found to be uncorrelated during pore collapse. (Edited author abstract). 13 refs.

**077867 PREDICTION OF RESERVOIR COMPACTION AND SURFACE SUBSIDENCE: FIELD APPLICATION OF A NEW MODEL.** A new loading-rate-dependent compaction model for unconsolidated clastic reservoirs is presented that considerably improves the accuracy of predicting reservoir rock compaction and surface subsidence resulting from pressure depletion in oil and gas fields. The model has been developed on the basis of extensive laboratory studies and can be derived from a theory relating compaction to time-dependent intergranular friction. The procedure for calculating reservoir compaction from laboratory measurements with the new model is outlined. Both field and laboratory compaction behaviors appear to be described by one single normalized, nonlinear compaction curve. With the new model, the large discrepancies usually observed between predictions based on linear compaction models and actual (nonlinear) field behavior can be explained. (Author abstract). 26 refs.

De Waal, J.A. (Koninklijke/Shell E&P Lab, Rijswijk, Neth); Smits, R.M.M. *SPE Form Eval* v 3 n 2 Jun 1988 p 347-356.

**077868 COMPARISON BETWEEN THE PRESSURE-LAG MODEL AND THE RATE-TYPE MODEL FOR THE PREDICTION OF RESERVOIR COMPACTION AND SURFACE SUBSIDENCE.** A theoretical study has been carried out to investigate whether the nonlinear compaction behavior of sandstone reservoirs, which has been reported for most well-documented field cases, can be explained by pressure lags in interbedding and/or neighboring low-permeability (shale) layers. On the basis of the results obtained, it is concluded that pressure-lag effects in normally encountered production scenarios cannot account for these nonlinearities, even under worst-case conditions. Therefore, the nonlinear field-compaction behavior must be caused by rate effects in the sandstone reservoir rock itself. This is supported by the fact that a rate-type compaction model recently introduced does indeed give a good description of the observed field behavior. (Author abstract).

Smits, R.M.M. (Koninklijke/Shell E&P Lab, Rijswijk, Neth); De Waal, J.A. *SPE Form Eval* v 3 n 2 Jun 1988 p 357-363.

**077869 ANALYSIS OF PRESTIMULATION TEST DATA IN DEVONIAN SHALE RESERVOIRS.** Prestimulation testing in Devonian shales has proved to be complicated because of the long duration of wellbore storage distortion that must be exceeded during flow and shut-in periods to obtain an analyzable test. This paper presents field examples of four prestimulation well tests that illustrate the practical difficulties in obtaining analyzable data. We were not able to analyze these tests with conventional semilog and type-curve methods. To understand the cause of the difficulties, we simulated a prestimulation well test to verify that the actual wells had not been produced long enough to exceed wellbore storage distortion. Guidelines are presented to aid in the design and implementation of a prestimulation test in Devonian shales. (Edited author abstract). 10 refs.

**077870 INTERFERENCE TESTING: DETECTING A CIRCULAR IMPERMEABLE OR COMPRESSIBLE SUBREGION.** A practical consideration of the effects of a single, circular, heterogeneous reservoir subregion on interference transient pressure testing is presented. The production well and the observation wells are external to the circular subregion. The internal circular boundary is considered as a constant-pressure source or as an impermeable subregion. The constant-pressure subregion has significant effects on interference pressure responses regardless of the size of the subregion. Ignoring the presence of a neighboring compressible portion of the reservoir, such as a gas or a steam cap, may yield erroneously high storativities and transmissivities. Multiple interference tests may suggest the probable location of the gas cap. The effects of an impermeable subregion are subtle, and in some cases, large, impermeable portions of the reservoir may not be detected by neighboring interference wells. (Edited author abstract). 20 refs.

**077871 PRESSURE TRANSIENTS AND CROSSLAYER FLOW CAUSED BY DIFFUSIVITIES IN MULTILAYER RESERVOIRS.** This paper considers single-phase unsteady flow in a system of homogeneous layers separated by thin, low-permeability shales, and having interlayer crossflow caused by different diffusivities for different layers. The model considers all layers open to a single well that flows at a constant total rate. Numerical simulations of the problem for the semipermeable-wall model are used to find the structure of the crossflows in typical cases. Analytic solutions for pressure and the n-1 diffusivity crossflows are developed and compared with the numerical results. These solutions show how the diffusivity crossflows depend on layer properties and ordering. Their behavior and properties are discussed and their effects on pressure distributions are shown. (Author abstract). 13 refs.

**077872 MECHANISM OF TRANSIT TIME INCREASE AND ITS INTERPRETATION AFTER WATER INJECTION INTO RESERVOIR M IN THE LAO JUN MIAO OIL FIELD.** Reservoir M in the Lao Jun Miao oil field is a very massive sandstone oil reservoir about 60 m [200 ft] thick. Within the reservoir, there are no evident shale barriers and no interlayer standard water zones. This reservoir is classified as a fractured porous reservoir. The reservoir rocks have a high shale content; montmorillonite is the main clay mineral with a maximum percentage content of up to 60 percent. This paper gives an idea of the mechanism for the increase in sonic transit time in flooded intervals of the reservoir on the basis of the measurement and analysis of the noninvaded cores. Study results show that the increase in sonic transit time after flooding is linked to the rock texture in relation to the high montmorillonite content. This paper also gives an in-house measurement technique for samples with high montmorillonite content. (Edited author abstract). 3 refs.

**077873 GAS BRINE CONTACT DETECTION BY SONIC WAVE VELOCITIES.** Shear wave velocities of dry and liquid saturated sandstone samples were measured at elevated reservoir conditions of pressure and temperature. Research as well as Biot's theory confirmed that the shear wave velocity decreased with the increase in liquid saturation and the dilatational wave velocity increased with the increased liquid saturation of the porous media. The ratio of shear to dilatational wave velocities for dry (gas saturated) sandstone samples was found to be higher than that of liquid saturated ones. Accordingly, this phenomena should be utilized in log interpretation as

a diagnostic feature to distinguish the gas-oil or gas-water contact in a subsurface formation. (Edited author abstract). 8 Refs.

**077874 NEW PRESSURE ANALYSIS TECHNIQUE USING REPEAT FORMATION TESTER DATA.** Current practice is to derive permeability from the pretest of wireline formation testers by the conventional Horner plot method. The major drawback of this type of analysis is the reliability of the flow time and flow rate estimates. A new technique to derive permeability from pressure response during the sampling period has been developed. The new method is based on the principle that at the end of the sampling period the volume of the fluid in the chamber is equal to the nominal volume of the sample chamber. The suggested method applies the approximation of the continuous pressure decline by a series of pressure steps as applied for water influx calculations. In its present form the technique has limitations due to flow regime shapes, number of phases present and the degree of formation damage. Research is underway to find acceptable solutions for the stated limitations. (Author abstract) 4 refs.

**077875 SYNERGISTIC EVOLUTION OF THE NORMAN WELLS RESERVOIR DESCRIPTION.** A major development drilling program at Norman Wells has seen 237 wells drilled since 1981. With this expansion, enhanced understanding of the reservoir has evolved from a synergistic treatment of the data base by geologists and engineers. Volumetric and flow capacity characteristics have been determined to provide a basis for managing the depletion of this crude oil reservoir. The development strategy implemented was a waterflood with pattern spacing and orientation designed to take advantage of the directional permeabilities associated with the fracture system. Geologic control has been integrated with performance data to describe the spatial variation in fracture-enhanced permeability. Comparisons of injection performance and core-derived permeability thickness data permitted quantifying the influence of the fractures on reservoir flow capacity. An areal map representing the effective flow capacity of the Norman Wells reservoir is assisting in the selection of workover candidates. (Edited author abstract) 5 refs.

**077876 PROCEEDINGS - SPE EASTERN REGIONAL MEETING.** This conference proceedings contains 40 papers covering an array of topics of interest to petroleum reservoir engineering. Papers on petroleum reservoir engineering, well test analysis, performance and production of oil and gas wells, and evaluations of Devonian shales are presented. Other topics discussed include oil field valuation, petroleum industry economics and legislation, enhanced oil recovery, pressure transients, production decline type curves, mathematical modeling, and production forecasting. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10492 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**077877 FORTESCUE RESERVOIR DEVELOPMENT AND RESERVOIR STUDIES.** The Fortescue field in the Gippsland Basin, offshore southeastern Australia is being developed from two platforms (Fortescue A and Cobia A) by Esso Australia Ltd. (operator) and BHP Petroleum. The Fortescue reservoir is a stratigraphic trap at the top of the Latrobe Group of sediments. It overlies the western flank of the Halibut and Cobia fields and is separated from them by a non-net sequence of shales and coals which form a hydraulic barrier between the two systems. Development drilling into the Fortescue reservoir commenced in April 1983 with production coming onstream in May 1983. Fortescue, with booked reserves of 44 stock tank giga litres (280 million stock tank barrels) of 43° API oil, is the seventh major oil reservoir to be developed in the offshore Gippsland Basin by Esso/BHP. (Edited author abstract) 2 refs.

**077878 METHOD TO DETERMINE SEMIPERMEABILITIES BY STEADY RATES.** This paper gives an analytical method to calculate the semipermeabilities for individual layers in an n-layer reservoir by using the steady layer rates when all layers produce together with a common wellbore pressure and a constant total rate. (Author abstract) 1 ref.

Gao, Cheng-tai (Chan-ting Oil Field Res Inst, China). *Soc Pet Eng AIME Pap SPE Unsolicited Manuscr Sep 1987 SPE* 017024, 3p.

**077879 EXACT SOLUTIONS FOR INFINITE-CONDUCTIVITY WELLS.** In pressure transient testing, the infinite-conductivity condition translates mathematically into a uniform-pressure (or uniform-potential) condition at the well. This means the flux at different points of the well should be determined in such a way that potential remains uniform at the well. The integral equation for accomplishing this is solved analytically to yield the Laplace-transformed potential. For fractured-well problems, this leads to a relatively fast algorithm for drawing type curves directly on a computer screen. For limited-flow-entry problems, the analytical pressure expression can be used with the method of images to treat problems in reservoirs of finite thickness and/or areal extent. (Author abstract) 13 refs.

**077880 APPROXIMATE PARTIAL-PENETRATION PSEUDOSKIN FOR INFINITE-CONDUCTIVITY WELLS.** This paper presents a simple formula for the pseudoskin factor of a well with restricted flow entry where infinite conductivity is taken into account analytically. The author derives an equation which is based on the assumption of a line-source well. The introduction of a nonzero well radius causes an error that is small only if the well radius is small compared to the interval open to flow. Comparisons with previously published results are shown graphically and in tabulated form. 15 refs.

**077881 DEVELOPMENT OF AN EFFICIENT ALGORITHM FOR THE CALCULATION OF TWO-PHASE FLASH EQUILIBRIA.** This paper details the development of an efficient algorithm for the calculation of two-phase equilibrium in multicomponent hydrocarbon systems with an equation of state (EOS). A

number of numerical solution algorithms are evaluated for speed and robustness. To ensure generality, the composition used in the study range from a synthetic 3-component fluid to a real 20-component reservoir fluid, and the calculations are performed at different positions on the fluid-phase diagram. The results of the study are used in the construction of a stable and efficient algorithm. Although the method was developed with reservoir engineering applications in mind, it should also be applicable in chemical, process, and petroleum engineering. (Author abstract) 31 refs.

**077882 WELL SINGULARITIES IN RESERVOIR SIMULATION.** In this study, we examine the problem of relating the computed solution at a well in reservoir simulation to the actual bottomhole pressure (BHP) and the related questions concerning determination of an effective radius for the computed pressure. We provide a mathematical analysis of this problem from a slightly different standpoint than that used elsewhere. Our approach provides further insight into the nature of the singularity, the extension to multisingularities, nonuniform grids, and the development of related approximation techniques for radially symmetric nonhomogeneous problems. We present some fundamental new results based on the analysis. (Author abstract) 7 refs.

**077883 IMPROVED CALCULATIONS FOR VISCOUS AND GRAVITY DISPLACEMENT IN MATRIX BLOCKS IN DUAL-POROSITY SIMULATORS.** This paper presents two innovations to improve the mathematical representation of viscous and gravity displacement from matrix blocks in dual-porosity simulators. The first improvement accounts for viscous displacement and convective mass transport in matrix blocks caused by potential gradients in the fracture network. Computation time is not significantly increased compared with current dual-porosity simulators. The second improvement provides two computationally efficient methods to refine simulation of gravity displacement in the matrix. Examples show that the improvements are highly desirable in many situations. (Author abstract) 11 refs.

**077888 PRESSURE-HISTORY-MATCHING METHOD FOR DETERMINATION OF RELATIVE PERMEABILITIES.** A pressure-history-matching method for determining relative permeabilities was developed and verified in a one-dimensional (1D), analytical/experimental study. The matching method is based on a pressure history induced by injecting a gas (nitrogen in this study) into an incompressible-fluid-saturated porous medium. The analytical model uses relative permeabilities expressed as two-parameter functions of saturation. A parametric study with a finite-difference implicit pressure, explicit saturation (IMPES) solution of the analytical model showed that the relative permeabilities can be determined by matching pressure histories in three steps: (1) match calculated pressure history with measured pressure history during the initial period of 1% of the total injection time, (2) match calculated pressure history with measured pressure history during the final period of 1% of the total injection time, and (3) minimize differences between calculated and measured pressure histories at no fewer than three selected intermediate times. (Edited author abstract) 31 refs.

**077889 INTEGRAL APPROACH FOR DISCRETIZING THE RESERVOIR FLOW EQUATIONS.** An approach for discretizing the integral form of the flow equations in porous media is proposed. The method has the advantage of providing the correct block volume calculations and steady-state flow in curvilinear coordinates. The harmonic mean for permeability is also obtained from the discretization. The equations are developed for a general orthogonal curvilinear grid system in terms of the components of the metric tensor. (Author abstract) 16 refs.

**077890 PC PROGRAM CALCULATES OIL AND GAS PROPERTIES.** A basic program was developed for the IBM PC to calculate physical properties and formation volume factors for oil and gas reservoirs at various pressures. The program utilizes mathematical functions that represent the best fit for pressure-volume-temperature (PVT) correlations derived by empirical data. The program makes calculations for gas reservoirs (with and without condensate yields) and oil reservoirs. Results can be used for reserve calculations and as 'reasonable' input data for material balance or reservoir simulation. Results will be useful if the oil reservoir is under-saturated and the input GOR is the solution GOR at or above the bubble point. Calculations for pressures between initial reservoir

pressure and bubble point pressure are useful for simulation only. 8 refs.

**077891 A SIMPLE APPROACH FOR ESTIMATING AVERAGE RESERVOIR PRESSURE IN DEPLETION-TYPE RESERVOIR.** A simple approach is presented for estimating average reservoir pressure in solution-gas-drive reservoirs using data of two flow tests. The two general IPR equations developed by L.E. Couto are the basis of this work. With this approach, provided that certain data is available, one can estimate flow efficiency, skin factor and relative permeability to oil. Excellent agreement is shown between the estimated and actual results. A field example is solved to illustrate the use of the procedure presented. (Edited author abstract). 8 Refs.

**077892 DIGITAL FILTER FOR DATA SMOOTHING WITH APPLICATION TO RELATIVE PERMEABILITY ESTIMATION.** Automatic data acquisition systems that allow data to be sampled very rapidly can provide much more information from experiments than manual data sampling. Computer storage and work requirements for interpretive procedures for calculating rock properties from measured data, however, generally increase significantly with the number of data. Rather than choosing a sampling rate on the basis of work requirements of the interpretive procedure, we recommend sampling as frequently as possible. Improved estimates for data values to be used in the interpretive procedure can then be obtained by a smoothing process. We present a simple digital filter for data smoothing. We evaluate improvements in relative permeability estimates that may be obtained when the digital filter is used with data collected from displacement experiments. (Edited author abstract) 13 refs.

**077895 NEW APPROACH TO LIMITED COMPOSITIONAL SIMULATION: DIRECT SOLUTION OF THE PHASE EQUILIBRIUM EQUATIONS.** A new method for solving the phase equilibrium in limited compositional models is presented. It is a direct solution algorithm based on simplified thermodynamics and can be easily implemented in existing simulators to model such mechanisms as retrograde condensation, oil stripping by gas cycling, and miscible and immiscible gas drive. In field-scale studies, the simplification in phase behavior is more than compensated for by the increase in simulator efficiency. Examples are given to illustrate the method's use in large-scale gas cycling. (Author abstract) 9 refs.

**077896 CUSTOMIZED MINIMIZATION TECHNIQUES FOR PHASE EQUILIBRIUM COMPUTATIONS IN RESERVOIR SIMULATION.** This paper discusses a minimization algorithm for the solution of the Gibbs free energy minimization problem involving at most two phases. There are three major aspects to this paper. The first is the selection of descent directions and step lengths in order to handle the poorly scaled phase equilibrium problems associated with mixtures near bubble points and critical points. The second is the prevention of convergence to trivial solutions in both the Gibbs free energy minimization problem for two-phase mixtures and the associated phase stability test for single-phase mixtures. The third is the use of effective convergence criteria to obtain either the desired level of accuracy in the solution or the maximum accuracy allowed by the problem and the computer. (Author abstract) 43 refs.

**077897 ENTOELUNGSPROZESS IN GESCHITTETEN TRAEGERN.** [Effect of Flow Barriers on Waterflooding of Heterogeneous Reservoirs]. In this report the effect of flow barriers on waterflooding of heterogeneous reservoirs was studied. Three types of flow barriers were investigated: a horizontal discontinuous flow barrier, a vertical leaking fault, a high permeable flow channel. The results were obtained with a numerical simulation program, BETA II. The model considers gravitational, capillary and viscous forces. A systematic variation of the permeability distribution, crossflow, injection scheme and dip of the reservoir was used to study the sensitivity of the oil recovery versus the key parameters. The results underline the importance of crossflow and gravity forces for oil recovery in faulted reservoirs even when the mobility ratio is one. (Edited author abstract) In German. 23 refs.

**077898 COMPARISON OF IMPLICIT AND EXPLICIT METHODS FOR INTERPRETING DISPLACEMENT DATA.** Accurate estimates of reservoir rock properties, such as relative permeability curves, are desired for obtaining reliable predictions of reservoir behavior. There are two distinct approaches for interpreting unsteady-state coreflood data to obtain relative permeability estimates. The JBN and related methods are explicit methods, in that relative permeability values are computed explicitly from coreflood data. With implicit methods, relative permeability curves are adjusted until values computed with a mathematical simulation of the laboratory experiment match. 12 refs.

**077899 RESERVOIR SIMULATION IN OIL AND GAS FIELD DEVELOPMENT.** Oil and gas field development, particularly in offshore or remote locations, is expensive financially and in terms of scarce engineering skills. Computer modelling, especially reservoir simulation, is of great value in evaluating technical risks and in optimizing economic return. With the ever increasing power and accessibility of computing, reservoir simulation will be used even more extensively in the future. Developments in computer hardware and in numerical analysis over the past two decades, coupled with greatly improved measurement programs in the field, have now made simulation an accessible and valuable operational tool. **077902 VISUALIZATION OF LABORATORY COREFLOODS WITH THE AID OF COMPUTERIZED TOMOGRAPHY OF X-RAYS.** This paper presents the use of X-ray tomography to inspect a series of laboratory core-displacement tests. Saturation profiles in thin longitudinal planes of view (slices) in the core are followed as a function of time. Immiscible and miscible displacements in single core plugs and butted composite plugs are presented. Effects of heterogeneity of the core, dispersion of flood fronts, and end effects are observed and discussed. The technique has a large potential to improve the understanding of fluid displacement processes in laboratory core experiments. (Author abstract) 13 refs.

Hove, A.O. (Statoil A/S); Ringen, J.K.; Read, P.A. *SPE Reservoir Eng* v 2 n 2 May 1987 p 148-154.

**077903 PROPERTIES OF CAPILLARY FLUIDS AT THE MICROSCOPIC LEVEL.** Results are presented of experimental measurements of the properties of model reservoir fluids (water and hydrocarbons) at the microscopic and submicroscopic level—i.e., when they are confined in narrow spaces comparable to the pore sizes of reservoir rocks. Measurements of capillary forces (or pressures) were carried out for curved oil/water interfaces (menisci) of radii as small as 20 Angstrom [2 nm]. The results show that the capillary pressure is accurately given

by the Laplace equation for even the smallest pore radii of interest in waterflooding. The Kelvin equation describing the equilibrium radius of an oil/water interface has also been verified down to very small radii. (Edited author abstract) 23 refs.

**077904 STATISTICAL STUDY OF RESERVOIR PERMEABILITY: DISTRIBUTIONS, CORRELATIONS, AND AVERAGES.** We propose that reservoir permeability may be statistically distributed in a variety of ways. Two hypothetical cases of reservoir layering are statistically analyzed. This analysis suggests that a restricted family of functions - all related to the normal distribution - can be used to represent permeability distributions. The log-normal distribution is one member of the family. Several sets of field data are analyzed. The analyses show that (1) permeability data are not necessarily log-normally distributed, (2) all the permeability distributions considered are closely approximated by members of the proposed family of functions, and (3) improved porosity/permeability relationships result when the permeability distribution is known. (Author abstract) 23 refs.

**077905 RESTORED-STATE CORE ANALYSIS FOR THE HUTTON RESERVOIR.** Wettability is a major control parameter in multiphase flow analyses such as relative permeability. When such analyses are required, the native wettability of the reservoir must be maintained in the test plug. Special cleaning and restoration procedures are described for cores from the Hutton field, located in the U.K. sector of the North Sea. Plugs taken from Hutton cores were contaminated with invert-oil-emulsion drilling mud, which made them strongly oil-wet. By use of special cleaning methods, the surfactants from the drilling mud were removed, and the Hutton reservoir was subsequently shown to be only slightly oil-wet by use of relative permeabilities on plugs that had been restored to native wettability. It was also found that some sections of the Hutton cores were neutral-wet to slightly oil-wet even when clean, possibly because of the presence of coal. (Edited author abstract) 36 refs.

**077907 PARAGLACIAL AEOLIANITES: POTENTIAL NEW HYDROCARBON RESERVOIRS, GIDGALPA GROUP, SOUTHERN COOPER BASIN.** Facies analysis of core from the Gidgealpa Group has led to the first recognition of sandstones of aeolian origin in the Cooper Basin. The aeolian suite was recognised in core from the Merrimelia Formation penetrated by wells within the Merrimelia field. Potential hydrocarbon traps may occur at the top of the aeolianites, or within them beneath intraformational seals formed by muddy interdune facies. The recognition of an aeolian suite at Merrimelia indicates the potential for similar facies development elsewhere in the southern Cooper Basin. Locally these could form important reservoirs beneath the level of existing production. (Edited author abstract) Refs.

**077908 PALM VALLEY - A CASE FOR INTERPRETATION, 1965-1984.** During the past 18 years, estimations of reserves of the Palm Valley gas field were the subject of many unpublished studies and one that was published in the Journal of Petroleum Technology by Strobel, Gulati and Ramey in 1976. In this study, a reservoir simulator was used to formulate a model that matched the observed pressures in both wells. Except for the reservoir area, all of the reservoir parameters derived by Strobel from the interference test data were used. The results show that the Palm Valley reservoir contains between 262 and 356 billion standard cubic feet of gas-in-place in the fracture system and the higher permeability matrix rock. Based on our model and including gas in the tight matrix, it is quite possible that the total gas-in-place ranges between 726 billion standard cubic feet and 1.106 trillion standard cubic feet. (Edited author abstract) 3 refs.

## Costs

**077909 DEVELOPMENT OF AN OFFSHORE GAS-CONDENSATE RESERVOIR BY NITROGEN INJECTION VS. PRESSURE DEPLETION.** A conceptual study is presented of the development of an offshore gas-condensate reservoir by nitrogen injection vs. pressure depletion. Nitrogen injection could enhance condensate recovery, but requires additional capital investments and is more costly to operate. The results of the study indicate that nitrogen injection is a realistic alternative for pressure depletion, provided that the reservoir is not too heterogeneous and the reservoir fluid is sufficiently rich in condensate. Under these conditions, nitrogen injection could be as profitable as conventional pressure depletion and in addition may double the condensate yield. The business risk for nitrogen injection is greater, however, and for this reason governments should consider granting special tax and/or royalty reliefs for enhanced condensate recovery schemes. (Author abstract) 11 refs.

**077910 PERMEABILITY DISTRIBUTIONS IN RESERVOIRS.** Determining permeability distributions in reservoirs from data measured at wells requires conceptual models of how the rock properties vary between wells. It is usually observed that arithmetic averages of foot-by-foot horizontal permeabilities measured parallel to the bedding planes in the cores agree with permeabilities calculated from well tests. This is logical because arithmetic averaging assumes that flow occurs through the various strata parallel to the bedding planes. In this conceptual model, a consistent assumption is that vertical permeabilities measured perpendicular to the bedding planes should be averaged harmonically (in series) to reflect flow in the vertical direction in a zone between two continuous shales. 2 refs.

**077911 UNE APPROCHE ANALYTIQUE D'UN MODELE BLACK OIL DES ECOULEMENTS TRI-PHASES COMPRESSIBLES EN INGENIERIE PETROLIERE.** [Analytical Approach to a Black-Oil Model for Three-Phase Compressible Flows in Petroleum Engineering]. An analytical study is made of three-phase compressible isothermal flows in porous media, within the general framework of the secondary recovery processes of petroleum engineering, taking into account realistic boundary conditions. The pseudo-compositional black-oil model, which is studied, leads to a variational formulation of the problem: a strongly coupled system is obtained that includes an equation and an inequality which are degenerate quasi-linear parabolic expressions containing a nonlinear forced-convection term and a pressure equation which is locally elliptic or parabolic, depending on the evolution of the gas phase. The introduction of a unilateral problem arises from the nature of the governing equations describing the black-oil model, which depends locally on whether the gas-phase exists (saturated oil) or does not exist (sub-saturated oil), which leads to a free boundary value problem. To this problem, a time-discretized regularized problem is associated; it is proven that, within a functional precise framework, the latter is mathematically well-posed and has a physically admissible solution. (Edited author abstract) In French. 12 refs.

**077912 CONCEPT OF RELATIVE GANGLION VELOCITY AND GENERALIZATION TO OIL-BANK MOVEMENTS IN POROUS MEDIA.** This paper discusses a simple computational technique for determining relative ganglion velocity in a pore and its implication to the formation and propagation of an oil bank. The approach is based on a simple theory of the movement of a discontinuous oil droplet (ganglion) through a model pore. The analysis, based on a simplified conical geometric model, permits the development of expressions for relative ganglion velocity (velocity of the oil ganglion relative to the bulk liquid velocity) under various flow conditions. This parameter is essential for modeling waterflooding and/or EOR processes and facilitates the prediction of oil-bank movements. Results of the calculations indicate that faster oil-bank movements are attained when interfacial tensions (IFT's) are low and pressure gradients are high. (Edited author abstract) 4 refs.

**077914 NEW ANALYTIC MODEL FOR FRACTURE-DOMINATED RESERVOIRS.** A new analytic model for analyzing well test data from fracture-dominated reservoirs is presented. It is a concentric composite model with a finite-radius well located in the center. In the inner region the flow is assumed to be linear, and in the outer region the flow is assumed to be radial. Solutions are obtained analytically and type curves for ranges of dimensionless parameters are presented. The model can be used to find the extent and the flow parameters of the fractures near the well and the average values for the entire system provided that wellbore-storage effects do not mask the early-time data. (Author abstract) 18 refs.

**077915 PREDICTION OF DIMENSIONLESS PRESSURE DURING PRODUCTION FROM A CIRCULAR RESERVOIR WITH GENERALIZED BOUNDARY CONDITIONS.** To the authors knowledge, no one has published the situation in petroleum reservoirs with mixed boundary conditions, although such situations may arise in reservoirs adjoining aquifers. In this study, a similar problem is solved with a generalized form of the boundary conditions. The problem is solved in Laplace transform space and inverted numerically using the Stehfest (1970) inversion technique. A computer program is given to implement the algorithm. With the program, solutions to situations already solved as well as the more general boundary value problem can be produced. The computer program will be useful to petroleum engineers, hydrologists, and engineers working in the area of heat transfer. 4 refs.

## Research

**077917 RADIAL FINGERING IN A WATER-WET POROUS MEDIUM.** Radial displacement of a non-wetting fluid (paraffin oil) by a wetting fluid (water) was studied in a consolidated porous medium for a wide range of flowrates. The effects of injection flowrate on the displacement pattern were observed photographically, and the volumetric oil recovery at the breakthrough condition was measured. The experimental results indicate that the recovery versus flowrate curve can be divided into three main regions: (1) a 'capillary region' at low flowrates where capillary forces are dominant; (2) a 'viscous region' at high flowrates where viscous forces are dominant; and (3) an intermediate 'stabilized region' where capillary and viscous forces are of comparable magnitude. The experimental data for the number of fingers are compared with theoretical predictions and the so-called wettability number is calculated. The results are finally compared with previous data for systems of reversed wettability and the differences, which are very significant, are discussed. (Author abstract) 26 refs.

## Thermodynamics

**077918 RESERVOIR-FLUID PHASE BEHAVIOR AND VOLUMETRIC PREDICTION WITH EQUATIONS OF STATE.** The use of several cubic equations of state in predicting vapor/liquid equilibria and volumetric behavior of reservoir-like and real reservoir fluids is discussed, and the difference between these equations is examined. It is shown that these equations can reliably predict phase behavior of complex reservoir crude and gas-condensate systems away from the critical and retrograde regions. The cubic equations examined predict

nearly the same K values. The volumetric prediction, however, is different from one equation to another. (Edited author abstract) 35 refs.

## PETROLEUM TRANSPORTATION

**077919 SOME CAUSES OF ERROR IN MEASUREMENT AND ACCOUNTING.** Apart from physical losses resulting from leakage, evaporation or fraud, 'losses' (and 'gains') can arise from mismeasurement. Bulk oil measurements cannot be precise and in all custody transfers one party will gain and the other will lose. When a bulk oil quantity is measured twice, differences will be disclosed which represent the net effect of many variations from the absolute. Differences of a minor nature are acceptable but abnormal discrepancies should be investigated.

**077920 LOSSES IN THE SHIPMENT OF CRUDE OIL: RECENT DEVELOPMENTS IN ANALYSIS AND QUANTIFICATION.** The underlying problem in the reconciliation of oil measurements for the purpose of loss control is the identification and quantification of real losses as opposed to apparent losses due to measurement error. An overall material balance provides a useful framework for analysis. The results of a pilot study of oil loss statistics derived from conventional voyage files for liftings of Middle East crude parcels during 1984/86 are presented. The factors which govern evaporative loss are discussed. The magnitude of crude evaporative losses during loaded passage is considered. There are grounds to suggest that evaporative losses of light ends during COW can produce a net penalty in NSV outturn. (Edited author abstract) 14 refs.

## Operations Research

**077923 EFFECTIVE METHODS FOR PETROLEUM TANK TRUCK DISPATCHING.** Two methods are described for dispatching and sequencing petroleum tank trucks used in the pickup and delivery of crude oil. The problem is similar to the multi-terminal vehicle dispatch problem except that each pickup at a well site must be followed by a delivery to an acceptable collection terminal. A greedy-type algorithm is developed which is

efficient for real-time dispatching. A subproblem optimization approach is also presented and computational results on test problems are reported. Lower bound calculations indicate that solution quality is often within 10 percent of optimality. (Author abstract). 14 refs.

**077925 SAPPHIRE-BEARING ULTRAMAFIC LAMPROPHYRE FROM YOGO, MONTANA: A OUCHITITE.** The Yogo lamprophyre dyke, central Montana, is the only known igneous rock from which sapphire is mined. The rock consists of subhedral grains of phlogopite and clinopyroxene set in a finer groundmass of mica, clinopyroxene, titaniferous magnetite and apatite within a mesostasis of chlorite, calcite, serpentine and rare K-feldspar. Pyroxene also occurs as polycrystalline aggregates. Phlogopite occurs as euhedral crystals that have been distorted during emplacement and subsequently deformed and altered. Sapphirite occurs as an accessory phase and is thought to be xenocrystic. Based on chemical and mineralogical evidence the Yogo lamprophyre is classified as a ouachitite. (Edited author abstract) 33 refs.

## Mixing

**077927 HYPERFUNC BASIC PROGRAM TO CALCULATE HYPERBOLIC MAGMA-MIXING CURVES FOR GEOCHEMICAL DATA.** Magma-modifying process is super-imposed on a mixed system and one element is plotted against another on a Cartesian diagram. A straightline joining the two end-member compositions results. Mixed rocks, representing different amounts of the two end-member compositions, plot in the same order on a petrochemical diagram, regardless of the element se-

lected. However, in ratio-element or ratio-ratio plots, mixing lines of a 'two rock system' related by a mixing process are represented by hyperbolic curves. A computer program has been designed to fit hyperbolic mixing curves to geochemical data using the equations developed by Langmuir and others. A hardcopy of the graphs that appear on the video display unit (VDU) can be printed. An example of input and output is presented. 7 refs.

## Peoples Republic of China

**077928 K-AR AGE AND STRONTIUM ISOTOPIC COMPOSITION OF THE TENGCHONG VOLCANIC ROCKS, WEST YUNNAN PROVINCE, CHINA.** Dating of 47 samples of the Tengchong volcanic rocks gave K-Ar ages ranging between 0.09 and 17.84 My. The  $^{40}\text{Ar}/^{36}\text{Ar}$  vs  $^{40}\text{K}/^{36}\text{Ar}$  plot was made on the basis of those data in which radiogenic  $^{40}\text{Ar}$  is more than 2%. Four isochrones at 2.93, 0.81, 0.31 and 0.13 My were then obtained. The eruption time was from the Miocene to Pleistocene, with the climax occurring in the Late Pleistocene. The K-Ar ages were determined by statistical analysis and the probability of eruptions indicates that the Tengchong volcanoes are not to be considered extinguished but dormant volcanoes. Rb and Sr contents and the strontium isotopic compositions were determined on 20 samples of Tengchong volcanic rocks. The initial  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios range from 0.70578 to 0.71437. It would appear that the 'parent magma' is of deep origin ( $^{87}\text{Sr}/^{86}\text{Sr}$  near 0.706) and that it underwent a progressive contamination by crustal material rich in radiogenic  $^{87}\text{Sr}$ . (Author abstract) 36 refs.

**077930 LAGRANGE-LIKE STABILITY OF LOCAL CYCLES TO A CERTAIN FORCED PHASE-LOCKED LOOP DESCRIBED BY THE THIRD-ORDER DIFFERENTIAL EQUATION.** A periodically perturbed PLL system described by the third-order differential equation is considered. Sufficient conditions for the existence of local cycles and their Lagrange-like

stability are satisfied. (Author abstract) 5 refs.

Andres, J.; Strung, M. *Rev Roum Sci Tech Ser Electrotech Energ* v 32 n 2 Apr-Jun 1987 p 219-223.

**077931 PLL PERFORMANCE IN THE PRESENCE OF PHASE-SUM TERM.** Unlike classical PLL models, the effects of the phase-sum term due to the phase-detector are investigated. Since no universal analytical solution to this non-linear problem is known, a numerical evaluation was made assuming a perfect proportional-plus-integral loop filter. It was determined that pull-in time and pull-in range are altered by the phase-sum term. The pull-in range becomes unsymmetrical and one-sided finite. In the synchronized state the phase-sum term introduces a periodic phase and frequency jitter. With changes in system parameters, this jitter amplitude may grow until chaotic oscillations and no synchronization occur. For all stable conditions the pull-out range remains near its classical value. (Author abstract) 10 refs.

Durcansky, George (KFA, Juelich, West Ger); Janssen, Franz. *Frequenz* v 41 n 10 Oct 1987 p 261-266.

**077932 EXACT DESCRIPTION OF PLLs WITH EDGE-TRIGGERED PHASE DETECTORS.** The behavior of analog PLLs with edge-triggered phase detector, active proportional-plus-integral loop filter and frequency divider is unsatisfactorily described by the known theory, especially if the period of the input signal tends towards the time constant of the filter. The new model derived via a digital analysis describes exactly the time- and frequency response of the system under consideration. A proposed adjustment of loop gain which is easily performed in practice yields a linear demodulation behavior of the loop. The theoretical results are experimentally verified. (Author abstract) 7 refs.

## Sampling

**077941 PERFORMANCE IMPROVEMENT OF DPPLL'S IN NON-GAUSSIAN NOISE USING ROBUST ESTIMATORS.** Digital phase-locked loops (DPPLLs) operating in the presence of non-Gaussian noise are analyzed. The loop model developed here allows for multiple input samples during each loop sampling period, complex processing of the input sample set, and various noise distributions. In particular, six different robust estimators are used as processors of the input: there are the trimmed mean estimator, a one-step Huber M-type estimator, a novel M-type estimator, and three versions of a zero-memory nonlinear (ZNL) estimator. The tracking performance of a second-order DPPLL is simulated and analyzed for five different types of noise. Comparisons are made for signal-to-noise ratios ranging from 0 to -10 dB. It is found that the ZNL estimators provide performance superior to that of the other robust estimators, especially for noise densities that are heavy tailed. 25 refs.

McCain, W. Bruce (Harris Corp, Melbourne, FL, USA); McGillem, Clare D. *IEEE Trans Commun* v COM-35 n 11 Nov 1987 p 1207-1216.

## Stability

**077942 THIRD-ORDER DIGITAL PHASE-LOCKED LOOP WITH IMPROVED STABILITY.** When a signal from a moving source is received by a phase-locked loop (PLL), the input-signal frequency of the PLL often changes in a ramp-function state with a constant-frequency offset. The conventional perfect-integration third-order PLL has a serious problem of being unstable for small-amplitude inputs, and thus it cannot be used in practice in a low SNR environment. This paper proposes three types of stable perfect third-order digital PLL's (M-DPLL) which are independent of the input-signal amplitude. This M-DPLL realizes the perfect third-order behavior by combining three first-order DPLLs using a digital signal processing technique. The excellent characteristics of this M-DPLL are confirmed by theoretical analysis and computer simulation. (Edited author abstract) 17 refs.

## Theory

**077943 FALSE LOCK AND BIFURCATION IN THE PHASE LOCKED LOOP.** New results are given on the phenomenon of false lock in phase locked loops (PLL). First, it is proved that for small values of closed loop gain  $\delta$ , there is only one function  $\omega_f(\delta)$  which represents the frequency error in a false locked Type I PLL. That is, there is only one false lock equilibrium point for  $\delta$  in a neighborhood of the origin. Furthermore, this equilibrium point is stable. The proof establishes that bifurcation of periodic solutions does not occur at  $\delta = 0$  in the nonlinear differential equation which describes the classical Type I PLL. Next, a perturbation-based method for analyzing false lock in Type I PLLs is given. The technique expresses  $\omega_f(\delta)$  and the periodic solution of the equation describing the false locked loop as power series in  $\delta$ . The algorithm is applied to the classical second order loop containing an imperfect integrator. (Edited author abstract) 10 refs.

## Analysis

**077945 DYNAMIC MULTICYCLE PHASE SHIFT MEASUREMENTS.** One problem of modern phasometry is the measurement of fast varying phase shifts in the presence of known and random impediments. At present the following methods are used for the measurement of the phase shift: method of separation of time intervals, based on fixing the moments of transition through zero; method of overlap, executing the logical function exclusive OR; compensation method realized with analog as well as numerical balancing; correlation method; and method of orthogonal processing of signals. It is argued that the method of separation of time intervals is the most suitable for dynamical multicycle measurements of the phase shift. This latter method is analyzed. 9 refs.

Gupalov, V.I. *Meas Tech* v 30 n 4 Apr 1987 p 375-379.

**Applications** See Also MAGNETIC MEASUREMENTS.

**077946 DYNAMIC PHASE METER FOR PROGRAM MATERIAL.** A method is described for a metering device that is capable of measuring the phase angle relationship of two audio program channels. A treatment of alternate techniques is given. Mathematical analysis shows how dynamic measurement can be performed. In addition, a circuit is realized and described that incorporates these techniques and allows for an indication of phase differences over an 80-dB range. Error sources of the meter are identified. (Author abstract).

## Calibration

**077947 PHASE METER CALIBRATION AT NBS.** To provide a phase meter calibration service, a phase angle calibration standard has been developed at NBS. This standard is a signal generator with two sinusoidal outputs and uses direct digital synthesis to generate the signals. The phase angle between the two sinusoids is determined by the input parameters in the calculation of the sets of digital values from which the analog output is synthesized. An auto-zero compensation mode corrects for residual phase differences in the two output channels. The phase resolution is better than 0.002° over a frequency range from 2 Hz to 5 kHz and 0.005° from 5 to 50 kHz. 10 refs.

Turgel, Raymond S. (NBS, Gaithersburg, MD, USA). *J Res Natl Bur Stand (US)* v 93 n 1 Jan-Feb 1988 p 53-60.

**077948 PRECISION CALIBRATION OF PHASE METERS.** Using the calibration of a phase meter with a nominally linear response as an example, a statistical approach is discussed for predicting worse-case offsets of the meter response characteristic from the value of the reference standard. A linear calibration curve is used to model the meter response, and statistical tests are described which test the appropriateness of the model and whether the calculated calibration curve differs significantly from the ideal. Various levels of corrections to be

applied can then be determined on the basis of these tests, and limits to offsets are calculated for each of the levels. By extending this approach, it is possible to predict limits of uncertainty when using the calibrated meter to make measurements. 6 refs.

Turgel, Raymond S. (NBS, Gaithersburg, MD, USA); Vecchia, Dominic F. *IEEE Trans Instrum Meas* v IM-36 n 4 Dec 1987, IMTC/1987: The Fourth IEEE Instrum and Meas Technol Conf, Boston, MA, USA, Apr 27-29 1987 p 918-922.

## Circuits

**077949 MICROWAVE PULSE PHASE METER.** A method is discussed for measurement of phase difference by means of phase detectors whose amplitude-phase characteristics are shifted by  $60^\circ$  relative to one another and form a measurement range of  $0-360^\circ$  with linear regions. Possible circuits that employ the method are analyzed. A digital microwave phase meter is described that was developed using one of the circuits to measure the phase difference of pulse signals. The nonlinearity of the digital readings of the phase meter at a frequency of 2795 MHz in the range of  $0-360^\circ$  is not over  $\pm 4^\circ$ . The analysis time is 2  $\mu$ sec. The minimum input-signal power is approximately 0.5 mw. (Author abstract) 8 refs.

## Digital Readout

**077950 HIGH-FREQUENCY SAMPLING ERROR OF AVERAGING DIGITAL PHASE METERS.** The high-frequency sampling error (HSE) of averaging digital phase meters (ADPM) based on phase shift-to-time interval-to-digital signal conversion for more than one input frequency period is due to the sampling error of a single phase time interval which builds up in the course of measurement. The HSE has a random nature since it depends on the random position of a single phase interval in relation to sampling pulses filling it and also on the input signal frequency  $F$ , sampling frequency  $F_0$ , and measurement time  $T_m$ . Difficulties with existing methods are pointed out and improvements are suggested. 3 refs.

Dolganov, M.V. *Meas Tech* v 30 n 4 Apr 1987 p 379-382.

**077951 UTILIZATION OF AN APPROXIMATION ALGORITHM IN A DIGITAL PHASEMETER.** The measurement of phase differences for narrowband processes that have amplitude and frequency modulation of complex form in a noise background cannot, as a rule, be executed by ordinary phase-measuring instruments. Obtaining estimates of the phase differences for the processes under consideration requires the creation of digital phase measuring systems and the development of appropriate algorithms. Elsewhere it was proposed to use an algorithm of discretely orthogonal processing of input processes to obtain estimates of the phase difference. This approach, undoubtedly effective, is proposed in this paper, to supplement the introduction of a subsearch in the frequency in order to expand the functional possibilities of the device. One of the variants of algorithms to estimate the phase difference using orthogonal processing can be based on solving problems of approximating the measured narrowband oscillatory process in a definite time interval by a model sinusoidal function. 4 refs.

Genkin, M.D.; Getmanov, V.G. *Meas Tech* v 30 n 9 Sep 1987 p 900-902.

**077952 NOVEL DIGITAL PHASE METER.** A simple digital phase meter using the dual-slope principle is described. It gives a digital output number independent of the input frequency or the clock frequency used for the measurement process. The meter performs its measurement within two cycles of the input wave. 3 refs.

Ibrahim, Khalid M. (Univ of Baghdad, Iraq); Abdul-Karim, Majid A.H. *IEEE Trans Instrum Meas* v IM-36 n 3 Sep 1987 p 711-716.

**077953 HIGH-PERFORMANCE DIGITAL PHASE COMPARATOR.** A digital phase comparator has been developed that is especially well suited to making precision phase measurements at high frequency. The circuit consists of two standard phase comparators that are interconnected so that their outputs are averaged to give the desired phase measurement. A clipping circuit consisting of back-to-back Schottky diodes is used to square up the output pulses, which improves the linearity. A variable-modulus digital prescaler is used to change the range from  $\pm 1$  fringe to  $\pm 32$  fringes. Instruments using this circuitry are being used to measure transient phase signals from a microwave interferometer that measures the plasma line density on the magnetic-fusion tandem mirror experiment. The resolution is less than 0.1 degree at a carrier frequency of 40 MHz with a maximum nonlinearity of 0.5%. 3 refs.

Coffield, Frederick E. (Lawrence Livermore Natl Lab, Livermore, CA, USA). *IEEE Trans Instrum Meas* v IM-36 n 3 Sep 1987 p 717-720.

**077954 NOISE-RESISTANT DIGITAL PHASE METER DESIGN.** A noise-resistant wide-bandwidth digital phase meter is described. The device is based on the phase compensation principle. A digitally controlled phase shifter, described in detail, is the main part of the circuit. The instrument readings are correct even for -6-dB signal-to-noise ratios. 10 refs.

Errors See MEASUREMENTS—Standards.

## Performance

**077955 ANALOG SELF-EXCITED PHASE-FREQUENCY CONVERTER.** In the course of development for information-measuring systems considerable attention is given to methods of forming measuring signals in which phase shift is an information parameter. Information concerning the physical quantities being measured in this case is obtained with phase meters. The accuracy of this kind of digital phase meters is affected substantially by the higher harmonic components of input signals and by the unavoidable attending additive noise. The degree of this influence has, in general, a complicated character and cannot be essentially reduced without changing the nature of the phase-shift conversion to a digital signal. The experimental results show that analog phase frequency converters increase the resolution of phase meters. 5 refs.

**077956 LOW COMPLEXITY ALGORITHM FOR THE DEMODULATION OF CONTINUOUS PHASE MODULATIONS.** Continuous phase digital modulations often present good spectral properties and low error probabilities. However, these modulation techniques require complex detection algorithms. In this paper, a detector algorithm with reduced complexity with respect to an optimum maximum likelihood detector is described. The complexity reduction is achieved by associating an additional information, called the reliability information, with each received symbol. A net reduction in the demodulation complexity can be obtained by using this algorithm. The performance of this algorithm is evaluated in the case of a correlative encoded FM scheme. (Author abstract) 16 refs.

## Analysis

**077957 CONVOLUTIONAL CODED CONTINUOUS PHASE MODULATION WITH PLURAL MODULATION INDICES.** The convolutional coding combined with continuous phase modulation (CPM) is known for its good tradeoff between coding gain and bandwidth. The multi-h modulation, i.e., the scheme in which plural modulation indices are in cyclical use, is introduced to obtain higher power efficiency. However the study of the combination of convolutional coding multi-h scheme has not been reported yet. In this study, we consider the combination of convolutional coded CPM with multi-h modulation to achieve larger Euclidean distance. We found that, in some cases, our proposed convolutional coded multi-h CPM can give considerable gains compared with those of conventional single-h scheme. (Edited author abstract) 6 refs.

## Equipment

**077958 MODULATOR PACKS MULTIPLE FUNCTIONS IN COMPACT CASING.** Packaging density drives most EW designs, especially those earmarked for airborne applications. Component and subsystem suppliers continually strive to achieve the greatest number of electrical functions in the smallest size. Many could take lessons from General Electric Co.'s Aerospace Electronic Systems Dept., whose A12/A13 LO synthesizer (LOS) phase modulator represents a textbook on how to integrate components. The A12/A13 LOS phase modulator contains a 5-b phase modulator, several stages of GaAs FET amplification, and numerous bandpass filters, powered by onboard voltage regulators.

Browne, Jack (Microwaves & RF, Hasbrouck, NJ, USA). *Microwaves RF* v 26 n 10 Oct 1987 p 151-152, 154-155, 157.

Mathematical Models See Also AUDIO ACOUSTICS—Synthesis.

**077959 CONVERSION OF PHASE MODULATION TO AMPLITUDE MODULATION USING A PHASE CONJUGATE MIRROR.** We predict that conversion of phase modulated light to amplitude modulated light takes place when two continuous monochromatic pumps and a phase modulated probe are mixed in a Kerr medium used as a phase conjugate mirror. The phase conjugate beam can be reshaped as a train of pulses when the probe phase is periodically modulated. Discontinuous phase jumps of the probe field are converted into dips in the temporal profile of the reflected beam. (Author abstract) 13 refs.

Optimization See AMPLITUDE MODULATION—Performance.

## Performance

**077960 PHASE MODULATOR WITH IMPROVED MODULATION-CHARACTERISTIC LINEARITY.** Rigorous requirements apply to phase modulators from the viewpoint of sensitivity, modulation-characteristic linearity, and level of stray amplitude modulation. These circuits are varicaps as control elements, so that they have a modulation characteristic that has but negligible slope and linearity of the modulation characteristic, and the stray amplitude modulation is also fairly high. We give a theoretical analysis of a phase modulator with unipolar transistor used as a control element that meets given requirements. 9 refs.

Nekrasov, I.S. *Radioelectron Commun Syst* v 30 n 9 1987

p 50-53.

**077961 METHOD FOR LINEARIZATION OF THE MODULATION CHARACTERISTIC OF AN ACOUSTO-OPTIC PHASE MODULATOR.** The AOPM described makes it possible to form radio signals with angle modulation over a wide range of variation in carrier frequency (tens-hundreds of megahertz) with a relatively broad spectrum of the order of 40-50%, determined basically by the frequency characteristics of the AOM used. The comparative simplicity of linearizing the modulation characteristic in a range of phase variation capable of substantially exceeding the most common interval of  $\pm 180^\circ$  used in conventional phase modulators makes the acousto-optic method of phase modulation considered promising for indirect production of frequency modulation. 2 refs.

**077964 ZUM RECHNERGESTUETZTEN ENTWURF VON PSK-DIREKTMODULATOREN.** [PSK-Modulators Designed by CAD Methods]. Computer-aided design tools are increasingly used in the product-oriented development of microwave circuits to eliminate cut and try methods and thus to achieve a reduction of costs and of time requirements. This trend is especially favoured, if microstrip circuits are considered, since meanwhile microstrip techniques have reached a certain degree of maturity, i.e., for many elementary microstrip structures, analytical mathematical models have become available. In this contribution the efficient application of the CAD to the design of reflection type microstrip PSK-modulators using PIN-diodes as switching elements is described. (Author abstract) 9 refs. In German.

Mueller, Fred-Egon (Standard Elektrik Lorenz AG, Pforzheim, West Ger). *Frequenz* v 41 n 10 Oct 1987 p 267-274.

**077965 ENCAP-4: AN OQPSK-TYPE MODULATION TECHNIQUE FOR DIGITAL RADIO.** A class of OQPSK-type signals (offset quadrature phase shift keyed) is defined which generalises several modulation formats. These signals are generated by means of a set of encoding rules which introduce a controlled amount of correlation between the in-phase (I) and quadrature (Q) components and between signal elements in each component. These encoding rules imply the specification of four generating functions directly related to the eye diagram of the I and Q baseband signals. It is shown that the proposed signal representation provides an efficient means of design and performance evaluation. Advantageous trade-offs between spectral efficiency and power efficiency can be achieved with some of the proposed signals, making them suitable for digital radio applications. (Edited author abstract) 11 refs.

**077967 ERROR PROBABILITY OF OFFSET DIFFERENTIAL PHASE SHIFT KEYING WITH INTERSYMBOL AND ADJACENT CHANNEL INTERFERENCE.** We compute the error probability for conventional and for symmetric differential phase shift keying (CDPSK and SDPSK) with differential detection in systems with binary, ternary and quaternary symbols and with two kinds of filters. In the first system the system response is a Butterworth filter with two, three and four poles, which causes both intersymbol interference (ISI) and noise correlation which depend on the normalized 3 db filter bandwidth B. In the second system the system response is a Nyquist filter with excess bandwidth. In this system we consider both ISI caused by errors in sampling time and adjacent channel interference (ACI) caused by a signal in a neighboring channel with frequency separation. (Edited author abstract) 24 refs.

**077977 PHENOLIC RESINS.** Phenolic resins, according to DIN 16916 part 1 are oligomeric condensation products of phenols and aldehydes (especially formaldehyde) and have been used for more than 75 years as solid or liquid binders and impregnating agents for the production of materials in a large number of fields of applications. They are distinguished by a favourable combination of physical and chemical properties, which they impart to the finished products in the cured stage. Because of their relatively low energy requirement, good blending properties and less dependence on oil, phenolic materials are also in future expected to exhibit good growth rates. Utilization of the typical thermoset properties - thermal, electrical and chemical property range - will additionally result in a further expansion of the fields of application of this group of plastics. 28 refs.

**077985 CATALYSIS OF THE BROMINATION OF PHENOLS AND PHENOXIDE IONS IN AQUEOUS SOLUTION BY  $\alpha$ -CYCLODEXTRIN.**  $\alpha$ -Cyclodextrin (CD) causes slight accelerations or retardations in the bromination of nine phenols and six phenoxide ions. Since CD forms fairly strong complexes with  $Br_2$ ,  $Br_3^-$ , and phenols, large rate reductions should be observed if the only reaction occurring involved free bromine reacting with free substrate. Thus, the results are consistent with a bromination pathway that is catalyzed by CD, and analysis of the kinetics shows that the reaction involves bromine, substrate, and one molecule of the cyclodextrin. Two pathways are plausible: A, reaction between free substrate and the bromine-CD complex; B, attack of free bromine on the substrate-CD complex. (Edited author abstract) 57 refs.

## Absorption

**077986 UPTAKE RATE OF PHENOL BY PSEUDOMONAS PUTIDA GROWN IN UNSTEADY STATE.** The uptake rate of phenol by washed cells of *Pseudomonas putida* grown on phenol in fermenter in an unsteady state, caused by the step increase of dilution rate and/or phenol concentration in the feed, was studied. The Monod-Haldane type equation was applied to fit the data and the best kinetic parameters were calculated by nonlinear least-square techniques. It was found that the minimum period of unsteady required for induction of the phenol metabolic pathway was approximately 30 min. The values of kinetic parameters in an unsteady state varied according to each parameter. (Edited author abstract). 13 Refs.

**077987 pH-WERT-ABHÄNGIGKEIT DER ADSORPTION VON PHENOL AN WINKLER-STAU.** [Dependence of the Phenol Adsorption at Winkler-Dust on the pH Value]. The parameters of the Freundlich-equation for the adsorption of phenol from an aqueous solution at Winkler-dust depend on the pH value. The effect is conditioned by the phenolate anion formed in accordance with the dissociation equilibrium and by its adsorbability being less compared with the undissociated phenol. The connections between the phenol load on the pH value can be described both by means of an empirical model and a mixture-adsorption model being physically and chemically founded by the IAS-theory. The developed mathematical relations permit the precalculation of the adsorption result in the case of a pH modification in phenolic effluents. (Author abstract) 8 refs. In German.

Tille, Anton (VEB Leuna-Werke 'Walter Ulbricht', Leuna, East Ger); Seidel, Andreas; Jobst, Wilfried; Schroeder, Lothar. *Chem Tech (Leipzig)* v 39 n 10 Oct 1987 p 445-447.

**077988 SURFACE DIFFUSION COEFFICIENT IN AQUEOUS PHASES ADSORPTION ON MACRORETICULAR ADSORBENTS.** The objectives of this study were to investigate the dependence of  $D_s$  on  $q$  for the adsorption of phenols on XAD-4 and XAD-7 from aqueous solutions, and to find the relationship between  $D_s$  (Surface Diffusivity) and  $E$  (Heat of Adsorption) by the use of one of the authors' equations. It is shown that the activation energy of the hole-making step ( $\beta$ ) was much larger than that of the jumping step ( $\alpha E$ ). Moreover, the surface of XAD-7 is more hydrophilic than that of XAD-4. Hence, in the case of XAD-7, a water molecule is more strongly adsorbed on the surface and more energy is required to produce a vacant site. However, the value of  $\beta$  is smaller for XAD-7 than for XAD-4. 10 refs.

Itaya, Akira (Yamaguchi Univ, Ube, Jpn); Fujita, Yuji; Kato, Nobuyuki; Okamoto, Ken-Ichi. *J Chem Eng Jpn* v 20 n 6 Dec 1987 p 638-640.

**077989 PENTACHLOROPHENOL SORPTION BY ORGANO-CLAYS.** Several clay organic complexes were prepared by placing organic cations on the exchange sites of smectite clays and studied as sorbents for pentachlorophenol (PCP). The organic cations used ranged from very hydrophobic in nature (e.g., dioctadecyldimethyl+ (DODMA)+ and hexadecyltrimethyl+ (HDTMA)+)-ammonium to those having minimal hydrophobic properties, such as tetramethylammonium+ (TMA+). In general, the more hydrophobic the cation on the smectite the greater the uptake of PCP from water. For those organo-clays containing small organic cations (e.g., TMA+), the organic phase consisted of separate small organic moieties, such as the methyl group. This phase did not act as an effective partitioning medium despite a significant carbon content, and very little PCP was taken up. Additional study results are discussed. (Edited author abstract) 16 refs.

**077990 BINDING OF PHENOLS TO ALUMINUM OXIDE SURFACES. 1. PHENOLS WITH A SINGLE HYDROXY GROUP.** The relative binding ability of each of a series of substituted phenols with an aluminum/aluminum oxide surface was determined through competitive adsorption experiments. The ability of each phenol to compete with acetic acid for surface sites, when coadsorbed from toluene onto a thermally evaporated aluminum surface, was determined. The resulting surface concentrations were determined primarily through changes in the water contact angle. The relative binding of the phenols was directly related to the acidity ( $pK_a$ ) of the phenol group in each molecule, with more acidic species having greater binding. All of the phenols, regardless of acidity, were less effective at binding than acetic acid. Meta and para substitution appears to influence binding only through the  $pK_a$  of the phenol group, while ortho substitution appears to lead to steric hindrance, with larger groups causing more hindrance.

Implications for design of phenol-containing adhesives are discussed. (Author abstract) 22 refs.

Holmes-Farley, Stephen Randall (Lord Corp, Cary, NC, USA). *Langmuir* v 4 n 3 May-Jun 1988 p 766-774.

**077991 ADSORPTION OF SUBSTITUTED PHENOLS ON ACTIVATED CARBON.** The adsorption of phenol and the substituted phenols, 4-nitrophenol, 2,4-dinitrophenol, 4-chlorophenol, and 2,4-dichlorophenol in aqueous solution, has been determined at 298 K on a series of activated carbons, prepared from olive stones having a wide range of burn-off (8-52%) and micropore size distributions. The adsorption process is controlled predominantly by the porosity of carbon when the microporosity is narrow in range. If the range of microporosity is wide then the adsorption process is affected by the chemical nature of the carbon and by the nature of the substituent group in the phenol. The adsorption isotherm of 2,4-dinitrophenol is a step function, which is interpreted as being due to the coexistence of neutral and anionic adsorbate species, and not due to a change in the orientation of the neutral adsorbate species. (Author abstract). 19 Refs.

Caturla, F. (Univ de Alicante, Alicante, Spain); Martin-Martinez, J.M.; Molina-Sabio, M.; Rodriguez-Reinoso, F.; Torregrosa, R. *J Colloid Interface Sci* v 124 n 2 Aug 1988 p 528-534.

**077992 STUDY OF THE POSSIBILITY OF INCREASING THE YIELD OF THE MONOALKYL-PHENOL END PRODUCT IN THE ALKYLATION OF PHENOL WITH  $C_8$ - $C_{10}$  OLEFINS.** It was found that the introduction of 2.5-3.0 wt.% dialkylphenols into the initial mixture leads to more complete utilization of the reagents used to obtain the end product - monoalkylphenol. When 3.0 wt.% dioctylphenol was introduced into an initial mixture consisting of 58 wt.% phenol and 34 wt.% olefin, the average concentration of dialkylphenol in four selected samples of alkylate amounted to 3.1 wt.%. It is concluded that alkylation of phenol is more economical when carried out in the presence of dialkyl derivatives. 6 refs. In Russian.

**077993 INFLUENCE OF STRUCTURE OF SULFONATED CATION EXCHANGE RESINS ON THEIR CATALYTIC ACTIVITY IN ALKYLATION OF PHENOL BY OLEFINS.** To determine the interrelation between catalytic activity and porosity characteristics of the sulfonated resins we tested various Soviet and foreign cation exchange resins prepared from styrene copolymers with 4-30% divinylbenzene. The catalytic activity of the resins was evaluated from the results obtained in alkylation of phenol by *n*-nonene and *n*-decene in two series of experiments. The macroporous resins with small quantities of divinylbenzene, with an overall catalytic activity that is quite high, give considerable quantities of alkyl phenyl ethers and little dialkylphenols (particularly with excess phenol), whereas the resins with 15% or more divinylbenzene in the polymer matrix give only small amounts of ethers and relatively large amounts of dialkylphenols. Both the alkyl phenyl ethers and the dialkylphenols have adverse effects on the quality of the monoalkylphenols and on products prepared from these materials, such as lube oil additives and water-soluble surfactants. The dialkylphenols can be removed cleanly by fractionation. Optimal activity and selectivity of catalytic action in the alkylation of phenol by higher olefins are exhibited by macroporous cation exchange resins of the KU-23 (10/60) type with  $W_0 = (2.4) \cdot 10^{-3} \text{ m}^3/\text{kg}$ ,  $r_m = (2.8-4.0) \cdot 10^{-8} \text{ m}$ , and  $W_0/r_m = (7-15) \cdot 10^3$ . 9 refs.

## Applications

**077994 CHELATING POLYMER-BEARING 4-(3-TRIAZOLYLAXO)PHENOL MOIETY AS THE FUNCTIONAL GROUP.** The polymer-bearing 4-(3-triazolylazo)phenol moiety was synthesized, and the metal adsorption properties of it for 6 divalent heavy metal ions ( $M^{2+}$ ):  $Co^{2+}$ ,  $Ni^{2+}$ ,  $Cu^{2+}$ ,  $Zn^{2+}$ ,  $Cd^{2+}$ , and  $Pb^{2+}$  were investigated. The object of this paper is to examine the effect of the donor oxygen atom of the hydroxyl group on the metal adsorption ability of the chelating polymer-bearing triazolyloxyphenol moiety, and to investigate the application of the polymer for removal of heavy metals from plating process solutions. 5 refs.

## Chemical Analysis

**077995 IDENTIFICATION OF METHOXYLATED PHENOLS AS CANDIDATE TRACERS FOR ATMOSPHERIC WOOD SMOKE POLLUTION.** More than 70 organic compounds have been identified in unfractionated methylene chloride extracts of soot from residential wood stoves by a combination of capillary gas chromatography coupled with low-resolution mass spectrometry (GC/MS), GC coupled with high-resolution mass spectrometry, and chemical ionization mass spectrometry with deuterated methanol as the reagent gas. Thirty of the species are derivatives of guaiacol (2-methoxyphenol) and syringol (2,6-dimethoxyphenol), which result from the pyrolysis of wood lignin. Soots from hardwood and pine show similar proportions of the syringol derivatives, but pine soot has much higher proportions of the guaiacol derivatives. These species are expected to be unique to wood smoke in urban atmospheres and are therefore suggested as tracers for atmospheric wood smoke pollution. (Edited author abstract). 29 Refs.

Hawthorne, Steven B. (Univ of North Dakota, Grand Forks, ND, USA); Miller, David J.; Barkley, Robert M.; Krieger, Mark S. *Environ Sci Technol* v 22 n 10 Oct 1988 p 1191-1196.

## Chemical Reactions

**077996 COMPOUND PROPERTIES RELEVANT FOR ASSESSING THE ENVIRONMENTAL PARTITIONING OF NITROPHENOLS.** Acidity constants, UV/vis absorption maxima, aqueous solubilities, octanol/water partition constants and ratios, vapor pressures, and estimated Henry's law constants are reported and discussed for 17 mono- and dinitrophenols. For substituted 2-nitrophenols in which intramolecular hydrogen bonding between hydroxyl and nitro group is not affected by proximity effects, the acidity constant  $K_a$  can be estimated from the Hammett relationship. For these nitrophenols, the aqueous activity coefficient of the nondissociated species is approximately independent of solute concentration, and a good correlation between octanol/water partition constant and aqueous solubility of the liquid compound is found. The electric effect of substituents on the octanol/water partitioning behavior of the dissociated 2-nitrophenols can be reasonably quantified by using Hammett substituent constants. Additional study results are discussed. (Edited author abstract) 37 refs.

**077997 KINETICS OF REACTIONS OF METHYL  $\alpha$ -ELEOSTEARATE WITH CRESOLS.** The kinetics of addition reactions between methyl  $\alpha$ -eleostearate which forms the main chain of tung oil and cresols when

catalyzed by an acid, p-toluene sulfonic acid, have been studied. The addition reactions, carried out with any one of the o-, m-, and p-cresols were shown to be first order with regard to both methyl  $\alpha$ -eleostearate and cresol concentrations. The reactions were additions of two cresol molecules to one methyl  $\alpha$ -eleostearate molecule, and it was presumed that they proceed in two steps in which the first step is rate-determining. (Edited author abstract) 24 refs.

**078000 UEBER DIE PHENOLISCHEN INHALTSSTOFFE HOCHSIEDENDER ANTEILE DES PHENOSOLVANEXTRAKTES AUS PROZESSWASSER DER THERMISCHEN VEREDLUNG XYLITISCHER BRAUNKOHLN.** [On the Phenolic Constituents of High-Boiling Fractions of the 'Phenosolvan' Extract Obtained from Effluent Liquors in Thermal Upgrading of Xylitol Brown Coals]. Separation and identification of high-boiling phenols of a 'phenosolvan' extract using temperature-programmed capillary gas chromatography combined with structure-specific reactions are described. More than 100 individual compounds are present, but only a few of them in greater quantities. The predominating phenol type is the pyrocatechols with 4-methyl-, 4-ethyl- and 3-methylpyrocatechols and the parent substance being the main components. Moreover, resorcinols, hydroquinones, alkylated monohydric phenols, phenolic ethers and phenolic aldehydes were detected and, in part, identified. The origin of the material under investigation is explained and potential uses as a source of phenols are discussed. (Edited author abstract) In German. 13 refs.

**078001 COMPARATIVE EVALUATION OF SOME METHODS OF INVESTIGATIONS OF THE COMPOSITION OF HYDROXYETHYLATED ALKYLPHENOLS.** An attempt is made in this study to use column fractionation, turbidimetric titration (TT), and gel permeation chromatography (GPC) for determining the molecular inhomogeneity of HEAP<sub>n</sub> (n=10) characterized by the molecular-weight distribution (MWD). It is shown that for operational control of the molecular and

structural inhomogeneities in the preparation of HEAP, it is desirable to use such methods as GPC and TT. The preference which should be given to GPC due to its rapidity and the volume of the information obtained is neutralized by the difficulty in procuring the instruments. For this reason, the availability and simplicity of the apparatus used is a favorable circumstance for the use of TT. 13 refs.

**078002 EFFECT OF ANODIC AND CATHODIC REACTIONS ON OXIDATIVE DEGRADATION OF PHENOL IN AN UNDIVIDED BIPOLAR ELECTROLYZER.** Both anodic oxidation and generation of hydrogen peroxide through electroreduction of oxygen may be useful for oxidative degradation of organic compounds present in the wastewater to be treated. To clarify the effect of electrode reactions of both sides of a bipolar plate on the current efficiency for oxidative degradation of phenol, experiments were conducted by using an undivided bipolar electrolyzer having a vertical stack of perforated graphite electrodes. The Faradaic current  $I_f$  was arranged as a function of the electrode potential difference  $E_B$  between opposite sides of a bipolar plate. By analyzing the  $I_f$ - $E_B$  curves for the electrolyses in solutions containing different reactants, separate currents corresponding to anodic and cathodic reactions were determined. (Edited author abstract) 10 refs.

**Dehalogenation** See Also CHLORINE COMPOUNDS—Biodegradation.

**078003 REDUCTIVE DECHLORINATION OF CHLORINATED PHENOLS IN ANAEROBIC UPFLOW BIOREACTORS.** The reductive dechlorination of chlorinated aromatic compounds was studied in anaerobic upflow bioreactors with chlorinated phenols as the sole carbon and energy source. Dechlorinating activity was maintained in three separate anaerobic bioreactors for 350, 400 and 190 days. Mineralization of approx. 40% of added chlorophenols to  $CH_4$  and  $CO_2$  was demonstrated. Substrate loading rates of up to 20 mg  $l^{-1}$  day $^{-1}$  at a hydraulic retention time of 2 or 4 days were achieved at a substrate conversion efficiency of >90% as determined by measurement of chlorophenol concentration in the effluent. The ability to degrade a mixture of all three monochlorophenols and 3,4,5-trichlorophenol was demonstrated. The majority of the active biomass was located at the bottom of the bioreactor in the form of a sludge blanket. Three microorganisms which dominated the biomass were identified by morphology as a putative anaerobic phenol-oxidizing bacterium, a *Methanosarcina* sp. and a *Methanotrix* sp. (Author abstract) 28 refs.

**Derivatives**

**078004 INTENSIFICATION OF THE PROCESS OF OZONATION OF NITRO DERIVATIVES OF PHENOL IN AQUEOUS SOLUTIONS.** Processes of ozonation of nitro derivatives of phenol - 4-nitrophenol, 2,4-dinitrophenol, 2,5-dinitrophenol, 2-methyl-4,6-dinitrophenol, and 2,4,6-trinitrophenol - are studied in the 2-11 pH range. It is shown that the relative reaction capacity of these compounds is determined both by the degree of their dissolution in solution and by the nature

of the aromatic ring substituents. The specific quantities of oxidizer required for decomposition of these compounds in aqueous media are found to be 4-8 moles of  $O_3$  per mole of the compound. It is shown that alkalization of the solution or combined presence of ozone with hydrogen peroxide of UV irradiation are ineffective as a means of intensifying the ozone oxidation process. (Author abstract) 11 refs.

**Desorption**

**078005 TEMPERATURE-PROGRAMMED DESORPTION OF PHENOL FROM OXIDE SURFACES.** Interactions between phenol molecules and surfaces of  $SiO_2-Al_2O_3$  (SA), MgO and  $ZrO_2$  were studied by using the temperature-programmed-desorption (TPD) method and infrared spectroscopy. Desorption of phenol gave a single peak in the TPD profiles of SA and  $ZrO_2$  at 363 and 783 K, respectively, but complicated profiles were found on MgO. A part of the adsorbed phenol was found to decompose to benzene and water at 803 K on  $ZrO_2$ , 853 K on MgO and above 873 K on SA. Desorption of water was also found below the decomposition temperatures; SA and  $ZrO_2$  gave a similar profile in which the water desorption peak appeared at around 473 K. No desorption of water was found on MgO at lower temperatures for MgO evacuated at 1073 K but a new peak appeared at around 538 K for MgO evacuated at 873 K. The difference in the desorption temperatures on the three samples was explained by considering the individual surface acid-base properties and OH concentration at the surface. The relative difficulty for phenol desorption and easiness for its decomposition on  $ZrO_2$  were interpreted in terms of its weak acid and weak base properties. (Author abstract) 6 refs.

**078008 SYNERGISTIC AND SALTING OUT EFFECTS IN EXTRACTION OF PHENOLS.** As a result of studying some features of extraction of phenol, cresols, and pyrocatechol with mixtures of solvents using directed actions which increase the distribution coefficients  $K_d$  (synergism, salting out, solvotropic effect), the constants of entry of the components of binary mixtures of extracting agents in mixed solvents were calculated and their composition was established. Regardless of the mixture of extracting agents used, synergism is manifested to a much greater degree in the extraction of *o*-cresol (ortho effect). The simultaneous effect of salting out and synergism with certain combinations of the parameters of the extraction system ensures almost total (96%) transfer of phenols to the extract. Addition of dialkyl phthalates in the phase of the extracting agent increases the efficiency of extraction of pyrocatechol from aqueous solutions by 1.5-2 times. 10 refs.

**078010 OXIDATION OF PHENOLIC COMPOUNDS BY OZONE AND OZONE+U.V. RADIATION: A COMPARATIVE STUDY.** This study was designed to investigate the reaction mechanisms of oxidation of various phenolic compounds by ozone and ozone+u.v. radiation at pH 2.5, 7.0 and 9.0. Experimental results indicated that the molecular ozone is the predominant oxidant only at acidic pH; at neutral and basic pH, in the absence or presence of u.v. radiation, free radical reaction is the major pathway in the oxidation of phenolic compounds. The overall removal of phenols and the removal of TOC increase with increasing pH during ozonation with or without u.v. light. For a specific pH, the removal rates of phenol and TOC are highest for ozone+u.v. light followed by ozone and then u.v. light alone. (Author abstract) 17 refs.

**078013 ANODIC OXIDATION OF 2,6-DIMETHYLPHENOL IN VARIOUS ELECTROLYTIC SOLUTIONS.** The electrolytic synthesis of poly(2,6-dimethyl-1,4-phenyleneoxide) (PPO), 3,3',5,5'-tetramethyl-4,4'-diphenylquinone (TMDDQ), and 2,2',6,6'-tetramethyl-1,1'-biphenol (TMBP) from 2,6-dimethylphenol in various electrolytic solutions was carried out. They were characterized by chemical (using IR absorption spectroscopy, <sup>1</sup>H- and <sup>13</sup>C-NMR technique, etc.) and electrochemical means. The results were compared with those obtained for the oxidative coupling of 2,6-dimethylphenol in the presence of oxygen using a copper-amine complex as the catalyst. On the basis of the results obtained, the possible mechanism of the anodic oxidation of 2,6-dimethylphenol is discussed. (Edited author abstract) 37 refs.

Oyama, N. (Tokyo Univ of Agriculture & Technology, Koganei, Jpn); Ohsaka, T.; Ohnuki, Y.; Suzuki, T. *J Electrochem Soc* v 134 n 12 Dec 1987 p 3068-3073.

**078014 ADSORPTION AND OXIDATION OF PHENOLIC COMPOUNDS BY IRON AND MANGANESE OXIDES.** The adsorption and oxidation of catechol and hydroquinone by Fe and Mn oxides has been investigated by Fourier transform infrared spectroscopic (FTIR) analysis of the adsorbed molecules and by the measurement of O<sub>2</sub> consumption by aqueous suspensions of these oxides. A model of surface oxidation by Mn and Fe is presented in which coordination of the organic at the surface is a prerequisite to electron transfer. Oxidation of organics can proceed with or without the uptake of O<sub>2</sub>, depending largely on pH, which determines the rate of reoxidation of the reduced metal ions by O<sub>2</sub>. The results emphasize the difficulty in interpreting the effects that chemical buffers have on oxidation reactions at oxide surfaces. (Edited author abstract) 33 refs.

**078015 OXIDATION OF AN INHIBITORY SUBSTRATE BY WASHED CELLS (OXIDATION OF PHENOL BY PSEUDOMONAS PUTIDA).** The specific uptake rate of phenol by washed cells of *Pseudomonas putida* grown on phenol in steady-state continuous culture at various dilution rates was studied. The Monod-Haldane-type equation was applied to fit the data and the best kinetic parameters were determined by nonlinear least-squares techniques. The values of the kinetic parameters were found to increase monotonically with the phenol concentration in the original chemostat. The relations between the values of kinetic parameters and phenol concentration in the chemostat were described by empirical equations. Then the equation governing the instant uptake of phenol by microorganisms in chemostat in the high conversion range of phenol was proposed. This equation together with the mass balance of continuous stirred tank biochemical reactors (CSTBR) utilizing phenol. (Author abstract) 10 refs.

**078016 LIQUID PHASE HETEROCATALYTIC OXIDATION OF PHENOL BY HYDROGEN PEROXIDE ON MAGNETITE.** We present the results of a study of the heterogeneous oxidation of phenol on iron

compounds containing the metal in the 2+ oxidation state. The selection of phenol as the model substrate was made because it is one of the most widespread, toxic, and difficult to remove environmental contaminants. Homogeneous catalytic oxidation of phenols by means of hydrogen peroxide leads to quite a high degree of purification of industrial sewage. The study has shown that magnetite, a natural material containing Fe<sup>2+</sup>, catalyzes the destructive, liquid-phase oxidation of phenol by hydrogen peroxide. The oxidation process takes place in two stages with a conversion of phenol to carbon dioxide up to 82%. 27 refs.

**078017 MECHANISTIC STUDY ON THE OXIDATION OF 2,6-DIMETHYLPHENOL BY DMAP\*-AND POLYSTYRENE-BOUND DMAP\*-BASED COPPER CATALYSTS.** A possible mechanism for the oxidation of 2,6-dimethylphenol by soluble and polystyrene-bound Cu(II)-DMAP catalysts is described. The work further shows that the phenol oxidation obeys Michaelis-Menten kinetics. For the Cu(I) reoxidation, an equilibrium is suggested in which molecular O<sub>2</sub> is reversibly bound to mononuclear Cu(I)-DMAP complexes, prior to Cu(I) dimerization and electron transfers. Combination of the results with generally accepted steps in the oxidation of phenols allowed the construction of a possible reaction mechanism for our particular system. **078018 LIQUID PHASE OXIDATION OF THIOPHENOL AND INDENE BY *t*-BUTYL HYDROPEROXIDE AND OXYGEN.** The *tert*-butyl hydroperoxide (tBHP) or oxygen initiated oxidation of thiophenol in the presence of the active olefin indene was examined in benzene at 120°C. The reaction is kinetically complex, but it was possible to relate the product distribution to a few competing reactions. The product mix was determined for several reaction time periods. The product slate was similar for all time periods, but yields of the individual components varied significantly with increasing reaction time. Gaseous products included isobutylene and a trace of methane. The major product from tBHP was *t*-butanol. (Edited author abstract) 29 refs.

**078022 STUDY ON CATALYTIC ACTIVITY OF  $\gamma\text{-Al}_2\text{O}_3$  IN AMMONIATION OF PHENOL.** The surface properties and catalytic activity of  $\gamma\text{-Al}_2\text{O}_3$  prepared from different raw materials as well as those modified by treating with HCl of different concentrations have been investigated. The surface properties were studied by TPD technique. Experimental results show that the existence of sodium ion on the surface restrains the surface acidity, and the catalytic activity is decreased. Sites of stronger adsorption appear on the surface, so the surface of this kind of  $\gamma\text{-Al}_2\text{O}_3$  becomes more heterogeneous than that of those without sodium ion. (Edited author abstract) In Chinese. 9 refs.

## Pyrolysis

**078024 PYROLYSIS OF 4-METHYLPHENOL IN THE PRESENCE OF CARBON DISULFIDE.** The goal of this investigation was to study the effect of carbon disulfide (as representative of sulfur compounds) on the process of thermal decomposition of 4-methylphenol - one of the components of coal phenols. It is shown that the process of pyrolysis of 4-methylphenol includes primary and secondary reactions. The presence of carbon disulfide results in a decrease in the partial pressure of the reacting materials, resulting in a decrease in the quantity of high-molecular compounds formed in the secondary reactions of polymerization and polycondensation. It was shown that the presence of carbon disulfide significantly accelerates the reactions of formation of benzene, toluene, and naphthalene. The presence of carbon disulfide has less effect on processes of formation of phenol, methyl-naphthalene, and diphenyl. 7 refs.

**078025 PYROLYSIS-MASS SPECTROMETRIC INVESTIGATIONS OF THE MECHANISTIC AND KINETIC ASPECTS OF THERMAL DEGRADA-**

**TION OF PHENOL-FORMALDEHYDE POLYCONDENSATES.** High-molecular-weight phenol-formaldehyde polycondensates, deuterium-labelled at the aromatic or methylene linkages, were subjected to pyrolysis in the direct insertion probe of a mass spectrometer or in separate pulse-mode pyrolysers interfaced to the mass spectrometer or to the gas chromatograph-mass spectrometer. The principal route of the thermal degradation in vacuum and in an inert atmosphere, involving the cleavage of phenol-methylene bonds and subsequent hydrogen abstraction and resulting in the ultimate formation of phenol and methyl-substituted phenols as volatile products, exhibited hydrogen-deuterium scrambling owing to the isomerization of the macroradicals. (Edited author abstract) 10 refs.

## Recovery

**078026 PHENOLANREICHERUNG DURCH PERVAPORATION.** [Phenol Enrichment by Pervaporation]. Following a brief introduction to pervaporation principles and membranes, results of a study to separate aqueous phenols by pervaporation are presented. Phenols, when volatile with steam, are enriched from dilute solutions using highly selective elastomeric membranes, and from concentrated solutions using moderately selective anion exchange membranes. Process variables, in addition to the nature of the membranes, are downstream pressure (selectivity) and temperature (flux). A two-stage process scheme for phenol recovery is proposed, combining pervaporation with phase separation of the enriched permeates. (Author abstract) In German. 4 refs.

## Reduction

**078027 DETERMINATION OF THE RATE CONSTANTS FOR A CECE REDUCTION MECHANISM.** We have made a generalized treatment of first-order kinetic processes in dc polarography, obtaining approximate analytic expressions, applicable to any conditions. This treatment is applied to the electrochemical reduction of O-nitrophenol, which undergoes a CECE mechanism in which both chemical stages influence the process simultaneously. All the rate constants involved in the process have been calculated. (Author abstract) 23 refs.

Heras, A.M. (Univ of Cordoba, Cordoba, Spain); Munoz, E.; Avila, J.L.; Camacho, L. *Electrochim Acta* v 32 n 10 Oct 1987 p 1495-1497.

**Removal** See Also SEWAGE TREATMENT—Activated Sludge; WASTEWATER—Biological Treatment; WASTEWATER—Treatment; WATER TREATMENT—Activated Carbon.

**078028 EFFICIENCY OF A COCURRENT CONTACT DEVICE IN A PHENOL-REMOVAL SCRUBBER.** The results of analysis of samples of tar supernatant in the circulating solution of sodium phenolates during testing of a cocurrent contact device, conducted without irrigation of the packing or a supply of fresh base for 3 days, are presented. According to the calculations, a depth of the gas-liquid layer of 0.25 m on a foam-swirl plate at a gas velocity in the device of 3.5 m/sec provides the same phenol distillation efficiency as a packing 5-6 m in depth. Thus, in order to minimize the size and weight of the device it appears most promising to design a device with three cocurrent contact devices in the absorption part of the device and three foam-swirl plates with total hydraulic resistance of 1.5 kPa in the description part. 5 refs.

**Separation** See Also SOLUTIONS—Separation.

**078029 ISOLATION OF TERT-ALKYLPHENOLS FROM THE PRODUCTS OF ALKYLATION OF PHENOLS.** A preliminary stage, flash evaporation of the reaction mass at 4-13 Pa for 5-15 min, is needed to prevent decomposition of tert-alkylphenols during their isolation from acid reaction mixtures by fraction. Flash distillation of high-boiling tert-alkylphenols should be conducted in presence of a component lowering the boiling point of the mixture, added in 1:(0.5-1.0) weight ratio of original mixture to the component. In the case of high-boiling compounds of low thermal stability, such as tert-dodecyl-phenols and tert-butylhydroquinones, flash evaporation was performed in the presence of a component boiling at a lower temperature than the main substance. The most suitable component for this purpose is phenol, but good results were also obtained with the use of alkylphenols. Results are also given of distillation, flash evaporation, and flash evaporation with a low-boiling component, of a reaction mixture containing hydroquinone, 2-tert-butylhydroquinone, and 2,5-di-tert-butylhydroquinone. 2 refs.

## Solvent Extraction

**078030 SYNERGISM DURING EXTRACTION OF PHENOL WITH BINARY SOLVENT MIXTURES.** Extraction of phenol with mixtures of n-butyl acetate with solvents of various classes, leading to a synergistic effect, was studied; synergism coefficients (S) were calculated. It was established that the synergism effect weakens with a decrease in the extracting effectiveness of the less active components of the solvent mixture. The dependence of S on the phenol distribution coefficients ( $K_d$ ) in the solvent mixture-water system and also on the number of carbon atoms (n) in the molecules of extractant homologs ( $C_5\text{-}C_{10}$  alcohols) is described by straight lines; equations of the lines  $S = b(K_d)$  and  $S = b(n)$  are presented. (Author abstract) 3 refs.

**Sorption** See Also ACRYLICS—Surface Properties.

**078032 CHEMISORPTION OF CATECHOL ON GIBBSITE, BOEHMITE, AND NONCRYSTALLINE ALUMINA SURFACES.** The mechanism of bonding of catechol and related phenolic compounds on aluminum oxides was elucidated from sorption behavior in the presence of competing adsorbates and the nature of the infrared spectra of the surface-bound molecules. The surfaces demonstrated a high degree of selectivity toward catechol, adsorbing the molecule in the presence of a large excess of chloride. Phosphate competed effectively with catechol for sorption sites while acetate did not. Catechol bound on the aluminum oxide surfaces was chemically

perturbed in much the same manner as catechol chelated by  $Al^{3+}$ , suggesting that the dominant sorption process involved the formation of a 1:1 bidentate complex with surface Al. The mechanism of bonding was similar for all the aluminum oxides, but the dominant crystal surfaces of the crystalline oxides were unreactive toward catechol, and adsorption was attributed to  $-AlOH$  groups situated on 'edge' faces. (Edited author abstract) 20 refs.

McBride, Murray B. (Cornell Univ, Ithaca, NY, USA); Wessellink, Lambert G. *Environ Sci Technol* v 22 n 6 Jun 1988 p 703-708.

## Spectrum Analysis

**078033 BINDING OF PHENOLS AND PHENOXY-IDE IONS TO CATIONIC MICELLES.** The proton NMR spectra of phenol, p-cresol, and p-ethylphenol bound to micelles of cetyltrimethylammonium bromide (CTABr) support binding adjacent to the cationic head groups. Anions of these phenols and of p-n-propylphenol and p-t-amyphenol also bind adjacent to the head groups. Changes in the chemical shifts of the hydrogen atoms of the surfactant due to interactions with the ring current of the solute are consistent with its inserting into the micelle rather than binding tangentially. (Author abstract) 33 refs.

## Toxicity

**078035 TOXICITY OF PHENOL TO ASELLUS AQUATICUS (L.) - EFFECTS OF TEMPERATURE AND EPISODE EXPOSURE.** The toxicity of phenol to the freshwater crustacean *Asellus aquaticus* was assessed by use of three response criteria (immobilization, paralysis and mortality). Median response times were longer (i.e. phenol appeared less toxic) at higher temperatures and reasons for this are discussed. Immobilized animals were able to recover from brief periods of exposure if placed in clean water, the rate of recovery being dependant upon exposure time, exposure concentration and temperature during exposure and recovery periods. The implications of this study for an understanding of pollution incidents are discussed. (Author abstract) 29 refs.

## PHENOXY RESINS

### Blending

**078038 SOLID STATE BEHAVIOUR AND PROPERTIES OF PLASTICIZED CELLULOSE ACETOBUTYRATE/PHENOXY BLENDS.** Blends of commercial plasticized cellulose acetobutylate (CAB) and the polyhydroxypropylether of bisphenol A (Phenoxy) were obtained in order to study the possibility of the plasticizer of the CAB to be distributed in the blend and to change the miscibility behaviour and the mechanical properties of the blends. During melt mixing the plasticizer of the CAB migrated to the phenoxy and changed the positions of the transitions of the blends. This change in the  $T_g$  values did not show any influence on the miscibility level. An antiplasticization process was evident, giving rise to higher modulus but poor ductilities in the blends. (Author abstract) 14 refs.

Jurado, M.J. (Univ del Pais Vasco, San Sebastian, Spain); Gaztelumendi, M.; Nazabal, J.; Mondragon, I. *Mater Chem Phys* v 18 n 4 Dec 1987 p 343-350.

### Degradation

**078039 SURFACE PHOTO-OXIDATION OF PHENOXY RESIN AND POLYETHERETHERKETONE.** The changes in surface chemistry of phenoxy resin and polyetheretherketone during photo-oxidation were monitored by ESCA. Extensive oxygen uptake was observed for both materials and the data showed that oxidation of the phenyl rings had occurred. Comparison of phenoxy resin with its acetylated derivative indicated that the changes in surface chemistry of the former during the initial stages of exposure were not due to the hydroxyl group. (Author abstract) 6 refs.

## PHONOGRAPH RECORDS

**078041 NO GUTS, NO GLORY: ENTREPRENEUR PLACES BIG BET ON CDS.** Revolutionary new digital audio compact discs (CDs), developed only five years ago, reportedly will completely replace traditional vinyl records as the dominant musical home entertainment media in the U.S. by 1995. This report describes the inside of Technetronics, and examines the philosophies driving the company's management style and manufacturing plan. Also included is a detailed report on Technetronics' exciting new third-generation CD manufacturing technology of the monoline. Rather than relying on complex methods to recreate a plant's environment to suit the disc during its critical stage of manufacture, Technetronics opted on shielding the disc itself from the normal environment of a plant. Hands-off automation is said to virtually eliminate damaging sensitive disc surfaces after metalization.

Processing See SIGNAL PROCESSING—Digital Techniques.

## PHONOGRAPHS

### Digital Devices

**078042 CD PLAYER TECHNOLOGIES.** CD players have rapidly been accepted since they were marketed because of their high sound quality. In order to enhance their features, some improvements have been made in CD technology by introducing new systems and developing new LSIs. In pursuing higher sound quality, high-fidelity reproduction of low-level signals and economy has been achieved by developing a 4-DAC 18-bit high resolution system and a CMOS DF/DAC LSI. As a result, a dynamic range of more than 100 dB, an S/N ratio of more than 113 dB, and a total harmonic distortion of less than 0.0025% have been attained. In pursuing operational convenience, signal processing of LSIs having a 'digital out' function and a peak level detecting function have been developed for compatibility with future digital audio systems and automation of tape dubbing. Also, a CD player system using these LSIs has been developed. The new technologies are mainly applied to the SL-P990/P770 Technics CD player. (Edited author abstract) In Japanese. 2 refs.

**078044 FLUXES OF NONEQUILIBRIUM PHOTO-EXCITED PHONONS ALONG SURFACES OF CRYSTALS WITHOUT AN INVERSION CENTER.** The flux of nonequilibrium phonons excited by light in the near-surface domain of a crystal or a thin plate is investigated. An exact expression is obtained for the phonon energy flux for a crystal with a polar direction and its polarization dependence is analyzed. The magnitude of the energy flux can reach the incident light intensity. The temperature difference produced by the flux of nonequilibrium photo-excited phonons is found. (Author abstract) 6 refs.

Blokh, M.D. (Novosibirsk Inst of Geodesy, Aerial Photography & Cartography Engineers, USSR). *Sov Phys J* v 30 n 7 Jul 1987 p 581-584.

**078045 STUDY OF THE ISOCHORIC FREQUENCY SHIFT OF THE PHONONS IN Al AND Cu.** The temperature dependences of phonon frequencies for Al and Cu have been measured under constant volume as a function of the wave vector  $k$  by means of inelastic neutron scattering. The isochoric condition was achieved by using high pressure. The common feature of the present results for Al and Cu as well as the previous results for solid Ne by Skalyo et al., is that the frequency shift for  $k$  less than  $0.5 (2\pi/a)$  can be expressed as  $-\alpha k/(1 + 3k^2)$ , where  $\alpha$  is inversely proportional to the melting temperature. This result can be understood by means of a nonlinear wave theory which is based on the modified Korteweg-de Vries equation. (Author abstract) 16 refs.

## Magnetic Field Effects

**078046 MAGNETIC-FIELD EFFECT ON THE PHONON ECHOES IN A RARE-EARTH-DOPED GLASS.** We have observed phonon echoes in a holmium-doped aluminosilica glass, down to 10 mK, up to 60 kOe, in the acoustic frequency range 450-800 MHz. The echo amplitude increases by a factor 3 as the magnetic field increases from 0 to 60 kOe. The magnetic field acts also on the phonon-echo decays. A saturation recovery experiment is reported. The tunneling-state-lattice relax-

ation time increases by a factor 6 as the magnetic field increases from 0 to 60 kOe. Relaxation of the tunneling states by the rare-earth ions is considered. (Author abstract) 23 refs.

Lerbet, F. (Univ Paris-Sud, Orsay, Fr); Bellessa, G. *J Phys (Paris)* v 48 n 8 Aug 1987 p 1251-1254.

## Mathematical Models

**078047 OPTICAL SOLITONS THROUGH AN HARMONIC VIBRATIONAL MODE.** An optic field interacting with an infrared active vibrational mode with a cubic nonlinearity is considered. The slowly varying envelope of the electric field is shown to satisfy the nonlinear Schrodinger equation. Various aspects of the model are discussed. (Author abstract) 15 refs.

## Spectroscopic Analysis

**078049 SPECTROSCOPY OF BALLISTIC PHONONS REFLECTED FROM A LEAD FILM IN INTERMEDIATE STATE.** The phonon reflection from solid-solid interfaces has been investigated by means of the heat pulse technique, but the contribution of the electrons is not yet understood. In order to clarify this role, we have studied the phonon reflection from a silicon-Pb film held in the intermediate state by a perpendicular magnetic field. We observed an increase in the intensity of the reflected phonons below the critical field. We interpreted this effect as a phonon reemission from the Pb film back into the crystal. (Edited author abstract) 14 refs.

## Spectrum Analysis

**078050 PHONONS RADIATED BY MOVING DISLOCATIONS IN DISORDERED ALLOYS.** Lattice dynamics calculations together with the Green's function techniques for disordered systems are used to describe the phonon spectrum radiated by a moving dislocation in a random alloy. The attenuation of these waves by scattering at the impurities and by excitation of local modes is evaluated. Large amplitude vibrations of the impurities are predicted and modification of the diffusion behavior in the neighborhood of the dislocation is suggested. (Author abstract) 16 refs.

Ramos de Debiaggi, S. (Centro Atomico Bariloche, San Carlos de Bariloche, Argent); Caro, A. *J Phys (Paris)* v 48 n 9 Sep 1987 p 1499-1504.

**078051 SCATTERING OF PHONONS BY VACANCIES.** The scattering of phonons by vacancies is estimated by a perturbation technique in terms of the missing mass and the missing linkages. An argument is given why distortion effects can be disregarded. The resonance frequency of the defect is sufficiently high so that resonance effects can be disregarded for phonons in the important frequency range for thermal conduction. The theory is applied to the thermal resistance by vacancies in cases where the vacancy concentration is known: potassium chloride with divalent cations, nonstoichiometric zirconium carbide, and tin telluride. ## PHOSPHATE DEPOSITS

### Africa

**078053 CARACTERISATION GRANULOMETRIQUE DU GISEMENT DE PHOSPHATE DU DJEBEL ONK IMPLICATIONS MINERALURGIQUES.** [Size Range Definition of the Phosphate Deposit of Djebel Onk Mineralogical Implications]. The size range definition of the phosphate ore of Djebel Onk reveals characteristic size range systems at 125  $\mu$ m and 450-630  $\mu$ m for the phosphate particles, as well as at 80  $\mu$ m for the dolomite and quartz elements. A study of the sequential evolution of these size range systems shows that their position is constant in the deposit and that merely the size range stock which they represent will vary. A knowledge of these characteristics of the size range permits the setting up of a flow sheet for the treatment which does not reach the standard temperatures of carbonate removal, thus preserving the reactivity of the ore. The result obtained in the laboratory on crude ore samples, assaying 22-23%  $P_2O_5$ , show a gain of 7-8%  $P_2O_5$  in the fraction of 100  $\mu$ m-1 mm which is of possible value. In French. 10 refs.

### Exploration

**078054 PHOSPHORITE MANIFESTATIONS IN THE NORTHERN PART OF THE POLAR URALS.** In the course of geological surveys and thematic studies on the western slope of the Polar Urals and in adjacent regions a whole series of phosphorite ore manifestations and deposits of various geological-industrial and genetic types was revealed. With respect to phosphorus content and reserves the manifestations of greatest interest are microgranular and nodular phosphorites of geosynclinal type and infiltration-Karst ores of weathering crusts. The outlook for the discovery of phosphorite ore deposits of these types on the eastern slope of the northern part of the Polar Urals (The Sob' River basin) is discussed. In Russian. 4 refs.

Shadrin, L.F.; Zudina, S.P.; Ostrovskii, L.Ya.; Kostyuk, M.A. *Razved Okhr Nedr* n 10 Oct 1987 p 20-22.

### Florida

**078055 RECOVERY OF PHOSPHATE FROM FLORIDA PHOSPHATE SLIMES.** The Bureau of Mines conducted tests on samples of two Florida phosphate slimes to devise a technique to recover phosphate currently discarded because of its fine size. A flotation technique was devised to recover the phosphate contained in two fractions of each slime: the plus 37- $\mu$ m fraction and

the plus 20- $\mu$ m fraction. The technique involved conditioning the flotation feed with sodium silicate and a fatty acid-fuel oil emulsion, floating a rougher phosphate concentrate, and cleaning the concentrate in two cleaner stages with sodium silicate added to each for gangue depression. Concentrates containing 21.0 to 32.3 pct  $P_2O_5$  were produced with recoveries of 68.1 to 84.2 pct of the  $P_2O_5$  contained in the flotation feed. (Author abstract) 7 refs.

**078056 DISTRIBUTION, TEXTURE AND COMPOSITION OF MODERN PHOSPHATE PELLETS IN PERU SHELF MUDDS.** Textural analysis, including estimates of concentrations of authigenic phosphate pellets, were made for right sediment cores from the Peru continental margin. Phosphatic pellets separated from these modern organic-rich sediments are black, spherical-ovoidal in shape, and in thin section often display a concentric structure around a nucleus consisting of inorganic mineral grains. Some pellets have a gray-white exterior coating which appears to be secondary diagenetic calcite. Phosphatic pellets account for upwards of 80 percent of the sediment mass in some cores. Pellets concentrate in specific size classes, generally between 125 and 500  $\mu$ m in diameter, and occur within a poorly sorted sediment. (Author abstract). 50 Refs.

Baker, K. Bryan (Florida State Univ, Tallahassee, FL, USA); Burnett, William C. *Mar Geol* v 80 n 3 pt 4 May 1988 p 195-213.

**078057 URANIUM-SERIES AND AMS  $^{14}C$  STUDIES OF MODERN PHOSPHATIC PELLETS FROM PERU SHELF MUDDS.** Recent sediments and separated phosphate pellets from the Peru shelf have been analyzed for uranium decay-series isotopes and  $^{14}C$  in order to determine age relationships and mineralization rates. Uranium-series ages of pellets separated from one box core are significantly higher than AMS radiocarbon ages determined for the same pellets. These differences appear to be a consequence of mixing of an older generation of pellets with ones which are more recently formed. High concentrations of phosphate pellets have accumulated in some Peru shelf sediments without extensive reworking. Individual pellets apparently form very quickly, on time scales of a few years. Estimated authigenic uptake rates of phosphorus into pellets ranges from 0.5 to 9.40  $\mu$ mol-P  $cm^{-2} yr^{-1}$ , somewhat higher than rates measured for nodules from the same area. (Edited author abstract). 30 Refs.

Burnett, William C. (Florida State Univ, Tallahassee, FL, USA); Baker, K. Bryan; Chin, Philip A.; McCabe, William; Ditchburn, Robert. *Mar Geol* v 80 n 3 pt 4 May 1988 p 215-230.

**078058 PETROLOGY AND MAJOR ELEMENT GEOCHEMISTRY OF PERU MARGIN PHOSPHORITES AND ASSOCIATED DIAGENETIC MINERALS: AUTHIGENESIS IN MODERN ORGANIC-RICH SEDIMENTS.** New petrographic and major element geochemical data from modern Peru margin upper slope-outer shelf phosphorites are presented, which provide insight into their origin and paragenetic relationship with other authigenic minerals (glauconite, pyrite and dolomite) occurring in organic-rich sediments. Glauconites are precipitated relatively early following the partial reduction of ferric iron and, following this process, phosphate, pyrite, and then dolomite precipitation take place at progressively deeper levels in the sediment in association with microbial reduction of sulfate. The phosphatic facies here consist of nodules, crusts, coatings and strata composed of phosphatic pelletal grains in association with organic-rich biosiliceous sediments. All are considered to have formed within a few centimeters or within a few tens of centimeters below the

sediment-water interface. Bacterial mediation may play an important, but as yet unspecified role in the precipitation process. Depth-stratified threshold carbonate ion concentrations may control the lower limit at which phosphatic minerals may precipitate. Additional aspects of the subject are discussed. (Edited author abstract). 130 Refs.

Glenn, Craig R. (Univ of Rhode Island, Narragansett, RI, USA); Arthur, Michael A. *Mar Geol* v 80 n 3 pt 4 May 1988 p 231-267.

**078059 RARE EARTH ELEMENTS IN THE PHOSPHATIC-ENRICHED SEDIMENT OF THE PERU SHELF.** Apatite-enriched materials from the Peru shelf have been analyzed for their major oxide and rare earth element (REE) concentrations. The samples consist of (1) the fine fraction of sediment, mostly clay material, (2) phosphatic pellets and fish debris, which are dispersed throughout the fine-grained sediment, (3) tabular-shaped phosphatic crusts, which occur within the uppermost few centimeters of sediment, and (4) phosphatic nodules, which occur on the seafloor. The bulk REE concentrations of the concretions suggest that these elements are partitioned between the enclosed detrital material and the apatite fraction. Analysis of the fine-grained sediment with which the samples are associated suggested that this detrital fraction in the concretions should have shale REE values; the analysis of the fish debris suggested that the apatite fraction might have seawater values. The REE pattern of the pelletal apatite suggests a seawater source and the absolute REE concentrations are relatively high. Subtle variations in the depositional environment might cause a significant variation in the REE content of this authigenic fraction of the sediment. Additional aspects of the subject are discussed. (Edited author abstract). 30 Refs.

## PHOSPHATE MINES AND MINING

**078060 POTENTIAL FOR MARINE MINING OF PHOSPHATE WITHIN THE U.S. EXCLUSIVE ECONOMIC ZONE (EEZ).** The U.S. phosphate industry has, historically, been the dominant world producer. However, the industry has recently been facing growing pressures by the exhaustion of low-cost land-based resources, foreign competition, unfavorable public policies resulting from environmental concerns, and attractiveness of alternative land uses. Even though phosphorus is not recognized as a strategic mineral, its important role in the production of inorganic fertilizer demands that special attention be given to the future of the industry. Survival of the industry in the future, in part, depends upon its successful application of a suitable mining technology, such as hydraulic slurry mining, to either the deep, high-grade, land-based resources, or the offshore deposits within the Exclusive Economic Zone (EEZ). Potentials of the offshore phosphate deposits of southern California, Georgia and North Carolina are compared. Based on the available geological knowledge, this paper identifies the deposits on the North Carolina continental shelf, especially the Frying Pan Area, as the most promising for exploitation in the near future. (Author abstract) 30 refs.

## Economics

**078061 ECONOMIC AND ENVIRONMENTAL COMPARISON: BOREHOLE MINING VERSUS CONVENTIONAL MINING OF PHOSPHATE.** An economic comparison of the borehole mining system with conventional dragline and bucket wheel excavator mining systems was completed at various mining depths and production rates. Hypothetical phosphate deposits, with various overburden thicknesses and reserve tonnage, are defined. Geologic conditions necessary for the application of the borehole system are identified. Discounted cash

flow analyses based on derived capital and operating costs are used to generate rates of return and product prices. (Edited author abstract) 14 refs.

Hrabik, J.A. (US Bur of Mines, Pittsburgh, PA, USA). *Trans Am Inst Min Metall Pet Eng Soc Min Eng AIME* v 280 pt A 1986 p 33-39.

## Florida

**078062 IMC'S PHOSPHATE MINES IN FLORIDA.** IMC Fertilizer Inc. is a wholly-owned subsidiary of International Minerals & Chemical Corporation, headquartered in Northbrook, Illinois. It is the world's largest private enterprise producer of phosphate rock and a major world producer of phosphate chemical fertilizers. The company's phosphate mining operations in Florida are reviewed with respect to geology, mining and milling operations including the phosphate fertilizer plant.

Anon. *Min Mag* v 157 n 5 Nov 1987 5p between p 444 and 451.

## Georgia

**078063 EVALUATION OF POTENTIAL RADON EXPOSURE FROM DEVELOPMENT OF GEORGIA PHOSPHATE DEPOSITS.** This paper estimates the magnitude of any radon-based health effects that might arise from future mining operations in selected areas of the Georgia coastal region. To do this, a calculational model was developed that took into account the mining operations themselves, the atmospheric dispersion of the radon released, and the radon daughter concentrations in nearby towns. The model was applied to both extremes. The first application was a hypothetical mining operation in Echols County. The second application was at a site near Savannah, Georgia. Both sites contain economically feasible phosphorite deposits. According to both calculations, there is very little health risk from such mining operations to the general public. 10 refs.

## Mathematical Models

**078064 ANALYSIS AND MODELING OF A PROPOSED MINING AND BENEFICIATION PROCESS.** The purpose of this research was to develop an analytic model of a proposed phosphate mine which could be used to predict the quality of the water within the system throughout the useful life of the mine. The water quality is determined by tracking the concentrations of various chemical ions at key locations in the mining and beneficiation process. In this paper we will describe the features of the proposed process, analyze the process and develop a nonstationary differential flow network model, discuss model assumptions and exogenous driving functions, compare steady-state model results with a laboratory simulation, and, finally, present dynamic modeling results. (Author abstract) 6 refs.

## PHOSPHATE ORE TREATMENT

Beneficiation See Also PHOSPHATE MINES AND MINING—Mathematical Models.

**078065 BENEFICIATION OF A DOLOMITIC PHOSPHATE PEBBLE FROM FLORIDA.** A different version of the modified Crago-TVA process was developed for beneficiation of a weathered dolomitic phosphate pebble from Florida. In this process, the phosphate

mineral first is concentrated with fatty acid and fuel oil in the overflow and then refloated to remove additional coarse dolomite in the underflow. The concentrate from the cleaner flotation stage then is subjected to conventional deoiling, but not silica flotation with amine. The remaining dolomite contaminant in the phosphate concentrate is finally floated as waste by using TVA's diphosphonic acid depressant process. (Edited author abstract) 7 refs.

Hsieh, Shuang-shii. *Ind Eng Chem Res* v 27 n 4 Apr 1988 p 594-596.

**078066 INTERACTION OF THE COMPONENTS OF PHOSPHATE ORES WITH DILUTE SULFURIC ACID SOLUTIONS.** This investigation was carried out in connection with development of methods for flotation and chemical beneficiation of phosphate ores. The experiments were conducted at 20, 40, 60, and 80° in the pH range of 1.5-4, with reaction times from 5 to 60 min. It is shown that an increase of pH is accompanied by decrease of  $K_v$ , which approaches zero at pH above 2.5. This is the region of practical significance for selective leaching of magnesium compounds from phosphate ores during flotation and chemical beneficiation. Intensive decomposition of shell rock begins at pH below 2.5, whereas dolomite is decomposed by sulfuric acid over the entire acidity range studied (pH=1.5-4). In order to achieve 60-80% decomposition of carbonates 10-20 min (pH=2-3) is sufficient, whereas at least 2 h is required in order to attain similar degrees of decomposition of shell rock at pH=1.5-2.5 refs.

Trushchenko, N.N.; Belyakov, V.A.; Pozin, M.E. *J Appl Chem USSR* v 60 n 8 pt 1 Aug 1987 p 1573-1576.

**078067 INNOVATIVE PROCESS FOR BENEFICIATION OF DOLOMITIC PHOSPHATE ORES.** In current phosphate beneficiation practice, double-float froth flotation is widely used for upgrading siliceous phosphatic ores. However, this process has generally been ineffective for beneficiating high dolomite/limestone phosphate ore because the fatty acid collectors used to float phosphate minerals also collect carbonate minerals. This work describes a new approach for selective fatty acid carbonate/phosphate flotation. The technique employed allows selective removal of carbonate gangue in the forth without the specific use of a phosphate depressant and without conditioning the pulp with the fatty acid collector. The samples tested were two dolomitic ores (Jhamarkotra, India and Guizhou, China), one dolomitic calcareous siliceous ore (Mussoorie, India) and a dolomitic siliceous ore (South Florida). 4 refs.

Anazia, Ibezim (Univ of Alabama, Tuscaloosa, AL, USA); Hanna, John. *Int J Miner Process* v 23 n 3-4 Jul 1988 p 311-314.

## Crushing and Grinding

**078068 WEAR OF 12 ALLOYS DURING LABORATORY MILLING OF PHOSPHATE ROCK IN PHOSPHORIC ACID WASTE WATER.** As part of its research on wear of mining and mineral processing equipment, the US Bureau of Mines evaluated the erosion-corrosion characteristics of 12 alloys in phosphoric acid waste water. Tests were conducted in ball mills by grinding phosphate rock in gypsum pond water with an initial pH of 1.6. For comparison, grinding tests were conducted in tap water. Static corrosion tests in gypsum pond water were also carried out. For all alloys tested, the wear by erosion-corrosion was greater than the sum of erosion plus static corrosion. A low-alloy high-carbon steel and a high-manganese nitrided stainless steel were the most cost-effective materials. (Edited author abstract) 4 refs.

Tylczak, J.H. (US Bur of Mines, Albany, OR, USA); Singleton, D.J.; Blickensderfer, R. *Trans Am Inst Min Metall Pet Eng Soc Min Eng AIME* v 280 pt B 1986 p 187-190.

**078069 MILL SIZING FOR PHOSPHATE GRINDING IN MILLS OF 0.2 TO 5 METERS IN DIAMETER.** The breakage parameters of phosphate ore were determined by batch first-ordering grinding studies in a laboratory ball mill according to the Austin, Klimpel, and Luckie procedures. The results were scaled to five larger mills of 0.56, 0.82, 3.36, 4.41, and 5 m in diameter assuming equilibrium ball charges for the full-scale mills. The results are used to predict product size distributions and capacities for batch grinding in the smaller mills and open circuit grinding in the larger mills. The Bond method gave capacity predictions that were 45% to 150% too high. (Edited author abstract) 16 refs.

Rogers, R.S.C. (SOHIO, Bridgeport, NJ, USA); Austin, L.G.; Brame, K.A. *Trans Am Inst Min Metall Pet Eng Soc Min Eng AIME* v 280 pt B 1986 p 240-246.

Decomposition See FERTILIZERS—Manufacture.

## Flocculation

**078070 FLOCCULATION OF FINE PARTICLES WITH POLYETHYLENE OXIDE: A PROPOSED MECHANISM.** Treatment of ores to recover metal and mineral values results in waste materials usually in the form of dilute slurries. The US Bureau of Mines investigated a technique for dewatering phosphatic clay waste by flocculating with polyethylene oxide (PEO) and dewatering the resulting flocs on a static screen and/or trommel screen. In the investigation, it was determined that PEO was superior to polyacrylamide polymers for this type of dewatering. This paper discusses reasons for this superior performance. 4 refs.

Scheiner, B.J. (US Bur of Mines, Tuscaloosa, AL, USA); Stanley, D.A. *Trans Am Inst Min Metall Pet Eng Soc Min Eng AIME* v 280 pt A 1986 p 2115-2117.

Florida See PHOSPHATE MINES AND MINING—Florida.

## Flotation

**078071 NEW FLOTATION APPROACH FOR CARBONATE PHOSPHATE SEPARATION.** Selective fatty acid flotation of carbonate gangue from sedimentary apatite was achieved under acidic pH conditions without specific apatite depressant and without conditioning the pulp with the collector. Concentrates (35% to 38%  $P_2O_5$ , 0.8% to 1% MgO) with high recoveries (80% to 85%) were produced from Indian and Chinese dolomitic ores. The calcareous and/or dolomitic-siliceous phosphate ores from Florida and Utah required two flotation stages for carbonate removal and the other for recovery from siliceous gangue. Preliminary tests with Florida ore gave concentrates analyzing 21%  $P_2O_5$  and 0.8% MgO, with a  $P_2O_5$  recovery of 76%. A Utah ore gave concentrates analyzing 35%  $P_2O_5$  and about 1% MgO, with a  $P_2O_5$  recovery of 76%. (Edited author abstract) 11 refs.

Anazia, Ibezim (Univ of Alabama, Tuscaloosa, AL, USA); Hanna, John. *Int J Miner Process* v 23 n 4 Nov 1987 p 196-202.

**078072 CONDITIONING OF FLORIDA PHOSPHATE ROCK USING A GRAVITY-FLOW MIXER.** A conventional paddle-type mixer and a gravity flow mixing device were evaluated for conditioning of fine phosphate feed (-35 + 150 mesh) with fatty acid and fuel oil and for acid scrubbing prior to cationic flotation. Gravity flow mixing required less residence time but slightly higher reagent concentrations to achieve recovery levels similar to conventional conditioning. Grade was less sensitive to reagent concentration using the gravity flow mixer. For acid scrubbing, the gravity flow mixer proved equally effective. In this paper, the effect of time, pulp density, reagent concentration, and emulsification on conditioning and acid scrubbing efficiency of the two devices is discussed. (Author abstract) 9 refs.

Moudgil, B.M. (Univ of Florida, Gainesville, FL, USA); Ransdell, J.C. *Miner Metall Process* v 5 n 1 Feb 1988 p 17-21.

**078073 FLOTATION OF DOLOMITIC IMPURITIES FROM JHAMARKOTRA (INDIA) PHOSPHORITES.** Flotation separation of dolomite from Jhamarkotra phosphorite ore deposit in India, has been achieved using the two-stage conditioning process. An alternate process using a proprietary reagent scheme has also shown considerable promise in removal of dolomitic impurities. Hallimond cell flotation of the 65 × 100 mesh size fraction using sodium oleate as the collector yielded concentrates containing 35%  $P_2O_5$  and 0.9% MgO with phosphate recoveries in the range of 80-90%. The above-mentioned processes have also been determined to be equally effective in separating dolomitic impurities from sedimentary Florida phosphate rocks. The mechanism of selectivity for the two-stage conditioning process has been attributed to the higher collector adsorption on calcareous ore during the first stage of conditioning and changes in the chemical nature of the adsorbed species upon reconditioning at a lower pH. (Edited author abstract) 13 refs.

Health Hazards See FERTILIZERS—Manufacture.

## Processing

**078074 DIGESTION OF PHOSPHATE ORE IN PHOSPHORIC ACID.** Phosphoric acid is used for fertilizer applications. To minimize environmental pollution by heavy metals, a new process is being designed. One of the important steps in this process is the complete digestion of phosphate ore in phosphoric acid. The rates of digestion of fluoroapatite particles in phosphoric acid were determined. The particle size was varied from 150 to 2000  $\mu$ m, the phosphoric acid concentration from 30 to 50 wt%  $P_2O_5$ , and the temperature between 60 and 90°C. The rate of digestion was found to be controlled by transport of calcium ions to the solution. A model for the digestion process was developed, based on the diffusion of calcium ions as the rate-limiting step. (Edited author abstract) 15 refs.

## Roasting

**078075 STUDY OF THE GAS-PHASE COMPOSITION DURING THE ROASTING OF PHOSPHORITE PELLETS.** Studies have confirmed the possibility of reducing the concentration of harmful components in the gases coming from the roasting zone by reducing the residual moisture content of the pellets arriving in the high-temperature zone. A sharp decrease in the moisture content of the pellets reduces the action of the most active defluorinating agent - water vapor - and leads to a reduction of the concentration of fluorine compounds in the flue gases. In Russian. 3 refs.

Talkhaev, M.P.; Gal'perina, S.Ya.; Borisova, L.I.; Botryakova, V.A.; Ustelmova, L.I. *Khim Prom* n 4 1987 p 216-219.

## Waste Utilization

**078076 NOVEL TECHNIQUE FOR THE RECOVERY OF COARSE NORTH CAROLINA PHOSPHATE.** A technique was devised by the US Bureau of Mines to recover coarse +1.2-mm (14-mesh) North Carolina phosphate now discarded as waste. Concentration utilizes the difference in particle sphericity between the relatively flat calcite and the rounded phosphate pebbles. Sizing, treatment in a continuous hydraulic classification system, and grinding upgraded a 17%  $P_2O_5$  reject to 24.5%  $P_2O_5$  with a phosphate recovery of 63%. The  $CaO:P_2O_5$  ratio was reduced from 2.49 to 1.66. (Author abstract) 4 refs.

**PHOSPHATES** See Also CALCITE—Crystallization; CARBON—Activated; FERTILIZERS—Packaging; GLASS—Optical Properties; LIPIDS; LIPIDS—Structure; URANIUM COMPOUNDS—Precipitation.

**078077 CHARACTERIZATION OF TRICALCIUM PHOSPHATE POWDERS PREPARED BY SPRAY-PYROLYSIS TECHNIQUE.** Crystalline tricalcium phosphate (TCP) was directly prepared by the spray-pyrolysis technique from ethanol-nitric acid solution of calcium nitrate and phosphoric acid. The concentration of the solution  $[(Ca^{2+}) + (PO_4^{3-})]$  was 0.05-1.0 mol/l. The spray-pyrolysis temperature ranged from 1100° to 1400°C. TCP powders of the  $\alpha$  form were obtained under all experimental conditions studied. When the temperature of the powders being produced in the reaction zone was lower than the  $\beta \rightarrow \alpha$  phase transformation temperature, metastable  $\alpha$ -TCP was obtained though the  $\beta$  phase is thermodynamically stable. On the other hand, stable  $\alpha$ -TCP was obtained when the temperature of the powders was higher than the transformation temperature. (Edited author abstract) In Japanese. 13 refs.

**078078 HYDRAULICITY OF THE DICALCIUM PHOSPHATE-CALCIUM CARBONATE MIXTURE AND PROPERTIES OF THE RESULTING POROUS APATITE.** Dihydrate ( $CaHPO_4 \cdot 2 H_2O$ ; DCPD) and anhydride ( $CaHPO_4$ ; DCPA) of dicalcium phosphate are studied on their hydraulicity (hydration and hardening) induced by the addition of  $CaCO_3$  and properties of the resulting porous apatite. The hardening was caused by the entanglement of microcrystals of reaction products, i.e., carbonate-containing apatite and/or octacalcium phosphate. DCPD is hydrated and hardens more easily than DCPA. The addition of  $F^-$  accelerates the hydration reaction remarkably, however no hardening occurs. The resulting hardened apatite bodies have 70-80% porosity and a diametral tensile strength of 0.3-1.5 MPa. Sintered apatite bodies prepared by heating the hardened bodies are densified to 45-60% and strengthened to 0.7-4.8 MPa. (Edited author abstract) In Japanese. 10 refs.

**078079 PHOSPHATE IN REINIGERN.** [Phosphates in Cleaning Products]. The lecture is concerned with builder systems of alkaline cleaning agents that are mainly based on phosphates and silicates. The cleaning agents dealt with are cleaning agents to be used in the industry or household and dishwashing agents. In addition to the cleaning effect corrosion and erosion effects and other interactions with the surface are considered. The prevention of incrustations, synergisms with other components and possibilities of preparing cleaning agents having special physical properties are also discussed. (Author abstract) In German.

**078080 STUDY ON SYNTHETIC METHODS OF TRIALKYL PHOSPHATE OXIDE AND ITS EXTRACTION BEHAVIOR OF SOME ACIDS.** Trioctyl phosphine oxide (TOPO) is useful for the extraction of many inorganic and organic compounds. A mixed trialkyl phosphine oxide (TRPO) is similar in property to TOPO. The total number of carbon atoms per molecule of TRPO ranges from 15 to 27. Three methods for synthesizing TRPO are described in this paper. Examinations of IR and NMR show that the complex interaction of  $P=O$  bond of TRPO with extracted substances is the same as that of TOPO. The distribution coefficients of phosphoric acid, citric acid, malic acid, oxalic acid, and tartaric acid with TRPO are reported. (Edited author abstract) 11 refs.

**078081 LITHIUM INSERTION REACTIONS OF  $KM_3P_6Si_2O_{25}$  POTASSIUM TRANSITION METAL SILICOPHOSPHATES.** Lithium insertion reactions were carried out on the potassium silicophosphates  $KTi_3P_6Si_2O_{25}$ ,  $KMo_3P_6Si_2O_{25}$ ,  $KMo_2TiP_6Si_2O_{25}$  and  $KSn_2TiP_6Si_2O_{25}$ . These reactions result in the formation of  $Li_xM_3P_6Si_2O_{25}$  phases with optimal stoichiometries of  $x = 2, 2, 2$  and 1, respectively. These compounds exhibit 3D intersecting tunnel structures. Lithiation does not result in any observable changes in the electronic conductivity of the hosts, which remain electronic insulators. Complex impedance measurements confirm that these compounds have relatively low activation energies for ionic conduction, in agreement with the observed ion-exchange properties. **078082 MARYLAND'S PHOSPHATE BAN - HISTORY AND EARLY RESULTS.** On May 28, 1985, Governor Harry R. Hughes formally signed into law a bill that prohibits the sale of phosphate detergents in the state of Maryland. This recent initiative, designed to help curb phosphorus over-enrichment, was one of several aimed at reversing the decline of Maryland's single greatest resource - the Chesapeake Bay. Analyses of early ban results reveal that influent phosphorus concentrations have dropped by nearly one-third at advanced wastewater treatment facilities operated by the Washington Suburban Sanitary Commission. The purpose of this article is to present the early results of the ban, cite the memorable events and turning points that paved the way for the ban, and briefly discuss what phosphorus over-enrichment is and why it is a problem in the bay. 5 refs.

**078083 THERMAL DISSOCIATION OF FLUORAPATITE IN PRESENCE OF SILICON AND TITANIUM DIOXIDES.** The purpose of this investigation was to study the influence of silicon and titanium dioxides on thermal dissociation of synthetic fluorapatite and of Oshurkovsk apatite concentrate. According to our experimental data, the degree of transfer of fluorine into the gas

phase during heat treatment of synthetic fluorapatite for 15 min in the temperature range 1773-1973 K increases from 8.5 to 61.3%. It has been shown by calculation and experimentally that joint presence of silicon and titanium dioxides in the mixture has a favorable effect on thermal dissociation of fluorapatite and native phosphate, lowering the temperature and raising the rate of transfer both of fluorine and of phosphorus into the gas phase. 11 refs.

**Fabrication**

**078085 PREPARATION OF FIBROUS HYDROXYAPATITE BY USE OF SODIUM ALGINATE.** Fibrous hydroxyapatite (HAP), which is expected to be used as an implant material to periodontal bone defects, was prepared by using sodium alginate (Na-Alg). The starting materials were prepared by dissolving  $Na_4P_2O_7$  into 5% Na-Alg. solution; Na-Alg./ $Na_4P_2O_7$  (weight ratio) = 2.4, 2.6, 2.8, 3.0, 3.2, while the mixed solution of 0.15 mol  $Ca(CH_3COO)_2$  and 0.1 mol  $CaCl_2$  was used as the spinning solution; pH = 6.0, 6.5, 7.0, 7.5. The starting materials were spun through a nozzle of 0.14 mm into the spinning solution in a vessel of 16 ml capacity. Gelatinous fibers obtained were aged, dried and calcined at 900°C for 1 hour. The thermal transformation of the calcined fibers and their compositions were examined by using X-ray diffraction, DTA, and chemical analysis. From these results, the optimum condition for preparing fibrous HAP was found to be as follows; Na-Alg./ $Na_4P_2O_7$  = 3.0, pH = 6.5. In order to remove pores appearing during the heating process, the dried fibers formed under the optimum condition were heat-treated under reduced pressure (at 133 Pa and 900°C for 3 hours). The resulting HAP fibers were about 30-40  $\mu m$  in diameter. It was also confirmed that the HAP phase in the fibers were maintained ever after heat-treated at 1300°C for 1 hour in air. (Edited author abstract) 15 refs. In Japanese.

## Ionic Conduction

**078086 IMPEDANCE MEASUREMENTS FOR SOME NASICON ANALOGUES.** New phosphates  $\text{Na}_2(\text{R}, \text{M}^{3+})\text{M}^{4+}\text{P}_2\text{O}_{12}$  and  $\text{NaM}_2^{2+}\text{ZrP}_3\text{O}_{12}$ , where  $\text{R} \equiv \text{La}, \text{Ce}$  or  $\text{Nd}$ ;  $\text{M}^{2+} \equiv \text{Ni}, \text{Cu}$ ;  $\text{M}^{3+} \equiv \text{Co}, \text{Al}, \text{Cr}$ ;  $\text{M}^{4+} \equiv \text{Ti}, \text{Zr}$ , were synthesized by the hydrothermal method. The crystals were subjected to impedance measurements and calculated activation energy, hopping rate, jump frequency etc. The ionic conductivity values in these compounds range from  $10^{-4}$  to  $10^{-1} (\Delta \text{cm})^{-1}$  at  $300^\circ\text{C}$  and the activation energy values for ionic motion range from 0.18 to 0.7 eV. In general the ionic conductivity in compounds containing zirconium is higher than in compounds containing titanium. (Author abstract) 7 refs.

## Leaching

**078087 LEACHING CHRISTMAS ISLAND C PHOSPHATE WITH SODIUM HYDROXIDE - A REVIEW.** Christmas Island C phosphate is an ore-overburden rich in phosphates of aluminum, iron, and calcium (c. 30%  $\text{P}_2\text{O}_5$ ; 25%  $\text{Al}_2\text{O}_3$ ; 12%  $\text{Fe}_2\text{O}_3$ ; 15%  $\text{CaO}$ ) and low in silica. A simple procedure was developed for leaching this material with sodium hydroxide solution at  $70^\circ\text{C}$ , filtering, and sequentially crystallizing pure trisodium phosphate and alumina trihydrate. Laboratory and pilot-plant work has developed a range of uses for the trisodium phosphate. Recently the alumina trihydrate crystallizing technique has been improved to allow direct production of smelter-grade alumina, with an adequately low phosphate concentration. The author briefly reviews each of these developments. (Edited author abstract) 29 refs.

## Manufacture

**078088 FLUOROVE EMISIE Z VYROBY TROJITEHO SUPERFOSFATU.** [Fluorine Emission from the Production of Triple Superphosphate]. The amount of fluorine released and emitted to the atmosphere from the production of triple superphosphate was measured. The decomposition of Jordan-type phosphorite by 70 per cent phosphoric acid proceeded at  $55^\circ\text{C}$ . Only 106.4 g F per one ton of  $\text{P}_2\text{O}_5$  is released, i.e., 0.3 per cent of fluorine present; 2.03 g F/ton of produced  $\text{P}_2\text{O}_5$  is emitted. (Author abstract) In Czech. 18 refs.

Violova, Anna (Chemicke Zavody J. Dimitrova, Bratislava, Czech); Hruzik, Dominik; Stefanka, Ladislav. *Chem Prum* v 37 n 10 1987 p 521-524.

**078089 PREPARATION OF HYDROXYAPATITE BY THE HYDROLYSIS OF BRUSHITE.** The conversion of brushite ( $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$ ; DCPD) into hydroxyapatite (HAP) by hydrolysis has been studied by separating the conversion process into two stages, i.e. the structural change of DCPD into HAP (I) and the subsequent compositional increase in Ca/P ratio of the HAP (II). Two-stage processing was reasonable and convenient for the preparation of stoichiometric HAP, because it was possible to manage the controlling factors in both Reactions I and II independently. The resulting HAP powders showed a comparatively low crystallinity similar to precipitated HAP and large weight losses (above 6%) on heating, and were composed of dense aggregates of irregular thin microcrystals. (Edited author abstract) 10 refs.

Monma, H. (Nat Inst for Research in Inorganic Materials, Sakura-mura, Jpn); Kamiya, T. *J Mater Sci* v 22 n 12 Dec 1987 p 4247-4250.

## Microstructure

**078090 MICROSTRUCTURE OF SEDIMENTARY PHOSPHATE FROM ISRAEL.** Phosphorites from the Zin and Arad fields near the Dead Sea in southern Israel are composed mainly of francolite (93-95 percent after beneficiation). Using mercury porosimetry and the BET method, it was found that the pores in the rocks are composed of three sizes; large (approximately 60  $\mu\text{m}$ ), medium (approximately 1  $\mu\text{m}$ ), and small (approximately 0.01  $\mu\text{m}$ ). The large and small pores have narrow size distributions, but that of the medium pores is very broad. Increase in the  $\text{CO}_2$  content of francolite is accompanied by an increase in the surface area and by a decrease in the mean size of the small pores. The small pores are also sensitive to calcination; they disappear above  $900^\circ\text{C}$ . (Author abstract) 10 refs.

## Optical Properties

**078091 LUMINESCENCE OF THE  $\text{Sb}^{3+}$  ION IN CALCIUM FLUORAPATITE AND OTHER PHOSPHATES.** Luminescence spectra and decay times of  $\text{Sb}^{3+}$  in  $\text{AlPO}_4$ ,  $\text{LaPO}_4$ ,  $\text{LiLaP}_4\text{O}_{12}$  and calcium fluorapatite ( $\text{Ca}_{10}(\text{PO}_4)_6\text{F}_2$ ) are reported. The luminescence properties of  $\text{Sb}^{3+}$  in  $\text{AlPO}_4$ ,  $\text{LaPO}_4$  and  $\text{LiLaP}_4\text{O}_{12}$  are explained by using existing models. The luminescence properties of  $\text{Sb}^{3+}$  in calcium halophosphate have been reported before, but were not completely understood. We find that a strong Jahn-Teller interaction is working on the relaxed excited state of the  $\text{Sb}^{3+}$  ion from which the luminescence properties can be explained. Evidence is given that  $\text{Sb}^{3+}$  in calcium fluorapatite occupies a  $\text{Ca}^{2+}$  site. (Author abstract) 24 refs.

**Phase Diagrams** See JOINTS, ADHESIVE—Degradation.

## Phase Transitions

**078092 SEQUENTIAL PHASE DEVELOPMENT OF  $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$  ON HEATING.** Recently, calcium phosphates have raised much interest mainly because they have potential for use as bio-materials.  $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$  is one of the most common compounds in the system  $\text{CaO}-\text{P}_2\text{O}_5-\text{H}_2\text{O}$  and is known as a precursor of hydroxyapatite which is useful for implants as teeth and bones. In this letter, the phase development of  $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$  on heating was investigated based on X-ray, infrared (IR) and electron spin resonance (ESR) analyses. The sequential phase development is summarized. As it is likely that the local structure around  $\text{Ca}^{2+}$  of the X phase is similar to that of  $\text{CaHPO}_4$ , the X phase would tend to form before the  $\gamma$  phase appears. 8 refs.

## Physical Properties

**078093 PHYSICAL PROPERTIES OF SOME MIXED PHOSPHATES FROM THE NATROPHYLLITE FAMILY.** Measurements of the temperature dependence of relative dielectric permittivity, electric sensitivity, and magnetic susceptibility of  $\text{NaMgPO}_4$ ,  $\text{NaCaPO}_4$ ,  $\text{NaNiPO}_4$ , and  $\text{NaCuPO}_4$  are reported. All follow a similar pattern, indicating the presence of two phase transitions, the nature of which has not been established. (Author abstract) 5 refs.

Dojicilovic, Jilaban (Univ of Belgrade, Belgrade, Yugosl); Napijalo, Milena; Napijalo, Milan; Novakovic, Lazar. *High Temp High Pressures* v 19 n 4 1987 p 431-435.

**Precipitation** See SOILS—Chemistry.

**Processing** See Also FERTILIZERS—Phosphates.

**078094 ENRICHMENT OF LOW-GRADE MAZIDAGI PHOSPHATES BY CALCINATION AND EXTRACTION METHODS.** Experimental results show that depending on particle size before calcination, time of calcination, temperature, and the methods of differentiation process after calcination, product concentrations were changed from 20 to 27 and 30 to 35%  $\text{P}_2\text{O}_5$ , respectively. By increasing the calcination time from 1 to 1.5 h at  $870^\circ\text{C}$  and using a sugar solution, and again removing the small particles, we were able to obtain products which were concentrated to about 34.5%  $\text{P}_2\text{O}_5$  with a yield of 78%. We regenerated the solution obtained at the end of these processes by passing  $\text{CO}_2$  gas through them and obtained powder  $\text{CaCO}_3$  with a purity of 99.6%. 6 refs.

Gunduz, T. (Univ of Ankara, Ankara, Turk); Gumgum, B. *Sep Sci Technol* v 22 n 6 Jun 1987 p 1645-1648.

**078095 VERMINDERUNG DES CADMIUM-GEHALTES VON ROHPHOSPHATEN UND MINERALDUENGERN.** [Reducing the Cadmium Content in Raw Phosphates and Mineral Fertilizers]. Processes have been developed to separate the Cd from the phosphate rock or from the crude phosphoric acids arising therefrom as intermediates. In this way, the Cd content of the phosphate rock can be reduced to less than 10% of its original value, and to 50% thereof by extractive treatment with acidic calcium nitrate solution. Older calcination processes for crude phosphate have been improved to give residual Cd contents of 10 to 50% at temperatures of 800 to  $1000^\circ\text{C}$ . Cadmium can be removed almost quantitatively from crude phosphate by means of dialkyl dithiophosphoric acid esters by extraction, binding to adsorbents, or ion flotation. Cadmium can be extracted from crude acids in high yield by long-chained amines. After partial neutralization of the crude acids, precipitation as cadmium sulphide is also possible. (Edited author abstract) 43 refs. In German.

## Separation

**078096 FLOTATION SEPARATION OF COLLOPHANE FROM DOLOMITE USING A 'METAL ION-HYDROPHILIC LIGAND' ADSORPTION METHOD.** Relying on thermodynamic calculations and the difference of bonding to some metal ions, the authors designed a metal ion-hydrophilic ligand method to separate collophane from dolomite. It employs some metal ions,  $\text{Fe}^{3+}$ , for example, to activate the adsorption of hydrophilic ligand onto collophane surface, and thus the collophane particles are made hydrophilic and depressed without evident effect on dolomite because of adsorbing little amount of  $\text{Fe}^{3+}$ . Separation results of batch flotation on artificial mixture of pure minerals (25.87 percent  $\text{P}_2\text{O}_5$  and 6.25 percent  $\text{MgO}$ ) have indicated that it is possible to recover a concentrate containing 37.1 percent  $\text{P}_2\text{O}_5$  and 0.6 percent  $\text{MgO}$  with 95.6 percent  $\text{P}_2\text{O}_5$  recovery, using  $\text{Fe}^{3+}$  - hydrophilic ligand as depressant. With the help of modern analysis methods, such as UV and X-ray photoelectron spectroscopy, the mechanism of the method has been studied and an adsorption model of  $\text{Fe}^{3+}$  - hydrophilic ligand on the mineral surface has been established. (Edited author abstract) 29 refs. In Chinese.

**078097 REMOVING APATITE FROM ULTRAFINE RHODOCHROSITE BY CONTROLLED DISPERSION - SHEAR FLOCCULATION FLOTATION TECHNOLOGY.** Based on controlled dispersion flotation and shear flocculation, a new approach for ultrafine particle is put forward. It is called controlled dispersion-shear flocculation flotation technology (CDSFF). Satisfactory results were obtained in experiments on pure apatite (-7.8µm 81.5 percent) and pure rhodochrosite (-6.9µm 83.67 percent). A product which contained 0.13 percent was obtained from the mixture containing the impurity 0.28 percent P in ultrafine apatite and rhodochrosite, and the recovery was 66.2 percent. Other technologies could not remove apatite as effectively as CDSFF. The mechanism of CDSFF was explored in detail by means of SME, AES, etc. (Edited author abstract). 6 Refs. In Chinese.

**078100 HIGH RESOLUTION SOLID STATE  $^{31}\text{P}$  NMR IN SOME ANTIMONY-PHOSPHATES.** antimony-phosphates have been studied by MAS high resolution solid state  $^{31}\text{P}$  NMR. Correlations have been drawn between NMR chemical shifts and structural data. They show that the  $^{31}\text{P}$  resonance line moves towards high field when the number of bridging oxygens in the  $\text{PO}_4$  group increases. The chemical shift anisotropy is related to the dimensionality of the solid network. It is smaller for 3D lattices. Water intercalation in layered phosphates leads to a shift of the  $^{31}\text{P}$  resonance towards higher or low field suggesting that protonation of some  $(\text{PO}_4)^{3-}$  group occurs. A correlation between the P-O  $\pi$  bonding and the chemical shift is also proposed. (Author abstract) 18 refs.

**078104 SOLUBILITY OF POTASSIUM HEXAFLUOROSILICATE IN AMMONIATED PHOSPHORIC ACID.** There are no reported data on the solubility of  $\text{K}_2\text{SiF}_6$  in the products of ammoniation of phosphoric acid. The experimental results show that when fluorine is precipitated in the form of  $\text{K}_2\text{SiF}_6$  from the products of WPA ammoniation the equilibrium concentration of soluble fluorine compounds in solutions containing 10-15%  $\text{P}_2\text{O}_5$  at  $\text{NH}_3:\text{H}_3\text{PO}_4$  ratios over 1.4 exceeds 0.45-0.64%. At  $\text{P}_2\text{O}_5$  concentrations above 20% in

ammoniated solutions their equilibrium fluorine concentrations can be maintained at a level below 0.1%; with the use of potassium compounds for defluorination of WPA in a combined process of purification and ammoniation of the acid (with 20-35%  $\text{P}_2\text{O}_5$  concentration) it then becomes possible to obtain fodder ammonium phosphates of certified quality. 10 refs.

**078105 PROPERTIES OF THE EXTRACTION SYSTEM  $\text{H}_3\text{PO}_4\text{-H}_2\text{SO}_4\text{-H}_2\text{O-TBP}$  AT 293-353 K.** Tri-n-butyl ester of phosphoric acid (tributyl phosphate, TBP) with its high temperatures of boiling and fulmination and low solubility in water and acids, is a promising extracting agent for use in processes for purifying extraction phosphoric acid of impurities. Earlier data on the system  $\text{H}_3\text{PO}_4\text{-H}_2\text{SO}_4\text{-H}_2\text{O-TBP}$  were obtained at a temperature of 293 K. With the possible temperature conditions of the process in mind, the equilibrium in this system at 293-353 K and the physicochemical properties of the organic phase have been studied. 10 refs.

**078106 QUATERNARY LIQUID-LIQUID EQUILIBRIUM: WATER-PHOSPHORIC ACID-1-PENTANOL-3-PENTANONE AT 25°C.** Liquid-liquid equilibrium, solubility and tie-line data, for the quaternary system Water-Phosphoric Acid-1-Pentanol-3-Pentanone, were obtained at 25°C and atmospheric pressure, using an analytical method. 1-Pentanol appears to be more effective than 3-Pentanol as extractant solvent of phosphoric acid. Advantages are not observed with the use of mixed solvents in the purification of wet process phosphoric acid by means of solvent extraction. (Author abstract) 5 refs.

**078107 LIQUID-LIQUID EQUILIBRIA FOR THE SYSTEM WATER-PHOSPHORIC ACID-1-PENTANOL-3-PENTANONE AT 25°C IN THE PRESENCE OF SODIUM CHLORIDE.** A quantitative study of the effect of sodium chloride has been made on the liquid-liquid equilibria Water-Phosphoric Acid-1-Pentanol-3-Pentanone at 25°C and atmospheric pressure. Mutual solubility and tie-line data are obtained at saturation of sodium chloride in both conjugated phases. The addition of sodium chloride increases the distribution coefficient of phosphoric acid and the selectivity of extractant solvents for 1-Pentanol and mixtures of 1-Pentanol and 3-Pentanol, whereas it has no significant influence when the extractant solvent is 3-Pentanol. (Author abstract) 9 refs.

**078109 FLUORIDE DISTRIBUTION COEFFICIENTS IN WET PHOSPHORIC ACID PROCESSES.** Phosphoric acid for use in fertilizer applications is mainly produced by digestion of phosphate ore, containing 2-4 wt% F, with sulfuric acid. During the digestion of the ore, the fluoride is released as hydrogen fluoride, which reacts with silica to produce fluoroaluminic acid. Part of this acid decomposes in  $\text{SiF}_4$  and HF, which on their turn partly evade into the air. These fluoride distribution coefficients were measured by saturation of a nitrogen gas stream passing through fluoroaluminic acid dissolved in mixtures of distilled water, chemically pure phosphoric acid, and sulfuric acid at various temperatures. A theoretical expression is derived, which allows calculation of the fluoride distribution coefficients between the acid and the ambient air between 70 and 95°C, for solutions containing 30-50 wt%  $\text{P}_2\text{O}_5$ , up to 6 wt%  $\text{H}_2\text{SO}_4$ , maximal 4 wt%  $\text{H}_2\text{SiF}_6$ , and a molar F/Si ratio of six. (Author abstract) 36 refs.

**078110 CONTINUOUS RECRYSTALLIZATION OF CALCIUM SULFATE DIHYDRATE TO THE HEMIHYDRATE IN THE PHOSPHORIC ACID WET PROCESS.** The authors examine the aggregation of hemihydrate crystals in acid phosphate solutions. In particular, they examined such factors as the concentration and temperature of the EPA, the  $\text{SO}_4^{2-}$  content of the solutions, the addition of a surfactant, the residence time of the slurry in the continuous recrystallizer, and the intensity of stirring, on the following indexes which characterize the recrystallization process: average dimensions of the hemihydrate crystal aggregates, porosity of the hemihydrate precipitate, filtration time, and the  $\text{P}_2\text{O}_5$  content of the precipitate. The effect of different surfactants on the properties of the hemihydrate aggregates obtained on recrystallization of dihydrate is presented in tabular form. It can be seen from these results that the presence of a surfactant led, in all cases, to a reduction in the amount of  $\text{P}_2\text{O}_5$  in the precipitate but at the same time only three of the eleven surfactants tested increased the average diameter of the aggregate particles. This indicates that surfactants do have a definite effect in reducing the capture of phosphate ion from solution by the crystallizing hemihydrate. 12 refs.

**078112 EFFICIENT GREEN-EMITTING LUMINESCENT MATERIAL:  $\text{Tb}^{3+}$ -ACTIVATED MONOCLINIC  $\text{Gd}_2\text{O}_3$ .** Monoclinic gadolinium oxide activated with  $\text{Tb}^{3+}$  is efficient green-emitting phosphor, even at low  $\text{Tb}^{3+}$  concentrations. Under X-ray excitation its efficiency is about 50% of that of  $\text{Gd}_2\text{O}_3\text{:Sb}$ . The low amount of blue  $^5\text{D}_3$  emission from  $\text{Gd}_2\text{O}_3\text{:Tb}$  is ascribed to the low-energy position of the 4f-5d band. The intensity ratio of the  $\text{Gd}^{3+}$  excitation lines in the photoluminescence excitation spectrum provides information on the location of the quenching sites. (Author abstract) 14 refs.

Blasse, G. (Univ of Utrecht, Utrecht, Neth); Dirksen, G.J.; Meyerink, A.; Terrell, D.R.; Neyens, L. *Mater Chem Phys* v 19 n 6 Jul 1988 p 547-556.

**078113 EFFECT OF  $\text{N}_2\text{-O}_2$  ANNEALING ON THE BLUE ELECTROLUMINESCENCE OF  $\text{Zn}_{1-x}\text{Mg}_x\text{S:Cu,Br}$  POWDER PHOSPHORS.** Stability of blue emitting AC electroluminescent (EL) powder phosphors of the type  $\text{Zn}_{1-x}\text{Mg}_x\text{S:Cu,Br}$  has been examined during annealing in static air, with a view to improving their lifetimes. The EL emission maximum is shifted from 436 (blue) to 520 nm (green) when annealed in  $\text{N}_2\text{-O}_2$  atmospheres of  $p_{\text{O}_2} \geq 0.01$  atm at 700°C. Under the same conditions, the solubility limit of  $\text{Zn}_{1-x}\text{Mg}_x\text{S}$  system decreases from  $x=0.24$  to 0.11. In  $\text{Zn}_{1-x}\text{Mg}_x\text{S:Cu,Br}$  phosphors, the phase content and the solubility limit are additionally dependent on the concentration of copper. The exsolution of MgS is probably due to the stabilization of the 3C phase by Cu and O. Annealing in  $\text{N}_2\text{-O}_2$  of  $p_{\text{O}_2} = 1 \times 10^{-3}$  atm increases the half-life of  $\text{Zn}_{1-x}\text{Mg}_x\text{S:Cu,Br}$  from approximately 150 h to approximately  $1.7 \times 10^3$  h. (Author abstract). 17 Refs.

**Additives**

**078114 EFFECT OF GADOLINIUM CONCENTRATION ON THERMOLUMINESCENCE OF DEFORMED  $\text{NaYF}_4$  PHOSPHORS.** The purpose of the present investigation was to study the 130°C peak in deformed  $\text{NaYF}_4$  phosphor as a function of gadolinium concentration. In view of the large size of the  $\text{Gd}^{2+}$  ion occupying the sodium or yttrium position in the lattice, there will be strong elastic interactions between  $\text{Gd}^{2+}$  ions and moving dislocations during the deformation process. Therefore, it is to be expected that in a specimen with sufficiently high concentration of gadolinium, the dislocation motion and multiplication will become nearly impossible. This, in turn, will suppress the production of vacancy clusters and dislocation dipoles. Such a situation will not favor the formation of 130°C centers. On the other hand, decrease in gadolinium concentration permits motion of the dislocations and the multiplication which is conducive to the generation of centers responsible for the 130°C glow peak. This explains the rapid fall in intensity of the 130°C peak as the gadolinium concentration is decreased. 12 refs.

**Analysis**

**078115 SURFACE ANALYSIS OF  $\text{Zn}_{1-x}\text{Cd}_x\text{S}$  PHOSPHORS EXPOSED TO UV LIGHT IRRADIATION.** Surface darkening of  $\text{Zn}_x\text{Cd}_{1-x}\text{S}$  phosphors induced by UV light irradiation has been studied using

Auger electron spectroscopy, x-ray photoelectron spectroscopy, and x-ray diffraction. It has been found that the light irradiation in a humid atmosphere forms sulfates and precipitates colloidal metals of Zn and Cd on the phosphor surface. The darkened surface due to the metal precipitate can be bleached to some extent when the phosphors are dried. (Author abstract) 3 refs.

**078116 THERMOGRAPHIC PHOSPHORS: PART II - AN ALTERNATIVE FOR SURFACE TEMPERATURE MEASUREMENT IN COMBUSTION ENVIRONMENTS.** The second part of the article discusses how the thermal phosphor method can be used to advantage over pyrometric techniques for surface temperature determinations in the presence of combustion flame. Advances in light sources, detectors, and associated electronics have made the method less expensive and more useful. Typically, a short-pulse-width (5 ns or less) laser is used to stimulate luminescence from a rare-earth-doped phosphor. The emission consists of sharp lines in the visible region of the spectrum. The duration (or lifetime) of the luminescence, as well as the amplitude, is temperature dependent. The rate of decay of this emission is exponential. By measuring the laser-induced fluorescence time constant of a sample of phosphor bonded to the surface of interest, it is possible to determine its temperature. An example of aerospace application of this method to measure the temperature of surfaces immersed in jet engine flames is presented.

**Bibliographies**

**078117 RESEARCH BIBLIOGRAPHY ON THE TEMPERATURE DEPENDENCIES OF THERMOGRAPHIC PHOSPHORS.** We have prepared a comprehensive research bibliography on the fundamental physics and engineering applications of thermographic phosphors. This bibliography is based on a survey of the literature cited in the Physics Abstracts over the past fifteen years. There are five major subject areas covered in this document. They are (1) phosphor spectroscopy, (2) the physical and chemical properties of ceramic phosphors, (3) methods of binding phosphors to various surfaces, (4) phosphor-based thermometry and (5) other applications of these materials to remote sensing and diagnostics. (Edited author abstract) 1 ref.

Dowell, L.J. (Univ of Virginia, Charlottesville, VA, USA); Gillies, G.T.; Allison, S.W.; Cates, M.R. *J Lumin* v 36 n 6 Mar 1987 p 375-376.

**Crystal Lattices** See LUMINESCENCE—Inorganic Solids.

**Degradation**

**078118 DEGRADATION OF PHOSPHORS UNDER CATHODE-RAY EXCITATION.** A systematic analysis of phosphor degradation is presented. An increase of the self-absorption of the luminescence, destruction of luminescence centres, a decreased energy flow to these centres, and increased energy losses in the phosphor host lattice - both in the bulk and at the surface - can be distinguished as causes of the deterioration of the external radiant efficiency of phosphors. Simple measurements are suggested to disentangle the contribution of each of these parameters to the observed degradation effects. As an illustration degradation effects of  $\text{Zn}_2\text{SiO}_4\text{:Mn}$ ,  $\text{Y}_2\text{SiO}_5\text{:Ce}$ ,  $\text{Sr}_2\text{Al}_6\text{O}_{11}\text{:Eu}$  and a  $\text{Tb}^{3+}$  activated borate glass are analyzed. ## Electronic Properties

**078119 EFFECT OF Mn CONCENTRATION ON ELECTRON EXCITATION IN ZnS:Mn ELECTROLUMINESCENT DEVICES.** In activated phosphors such as ZnS:Mn the brightness varies with the concentration of the activator, in electroluminescence in another way than in photoluminescence. A model is presented that explains this on the basis of a quenching term and an excitation term involving electron interaction cross sections in Mn. The model is consistent with observed brightness data and supports the findings of other work in ZnS:Mn. An estimate of the low-energy electron interaction cross section of Mn ions suggests a strong interaction to take place. (Author abstract) 10 refs.

Kitai, Adrian H. (McMaster Univ, Hamilton, Ont, Can). *J Lumin* v 39 n 4 Mar 1988 p 227-230.

## Garnets

**078120 SINGLE-CRYSTAL GARNET PHOSPHORS.** Single crystal garnet phosphors are considered for cathodoluminescent screens in cathode ray tubes (CRT) yttrium aluminum garnet activated with cerium (Ce:YAG). It was observed that this material overcame all the shortcomings for the powder phosphors. The single-crystal phosphor can be excited with a high-power electron beam to provide a display of uniform output and exceptional brightness with very little coulombic degradation. The material is capable of resolution equal to that of the exciting electron beam, and because of its nonscattering nature, it produces a very high contrast image. 4 refs.

Wittenberg, Albert M. (AT&T Bell Lab, Murray Hill, NJ, USA). *Inf Disp* v 3 n 5 May 1987 p 14-17.

## Hydrolysis

**078121 HYDROLYSIS REACTIONS OF CaAs PHOSPHORS.** Elementary processes of hydrolysis were studied on CaS:Ce and (Ca, Mg):S:Mn phosphors by ion chromatography. Analysis of a phosphor suspension solution has shown that oxidation of SH producing  $\text{SO}_3^{2-}$ , as well as formation of  $\text{CaCO}_3$  accelerates the overall hydrolysis. On the basis of these results, methods of suppressing hydrolysis were examined and used to develop a screening process for monochromatic tubes. (Author abstract) 6 refs.

**078122 GREEN PHOSPHOR BASED ON  $\text{CeAl}_{12}\text{O}_{19.5}$  ACTIVATED WITH  $\text{Mn}^{2+}$ -INCORPORATION.** The photoluminescence of  $\text{Mn}^{2+}$  in  $\text{Ce}(\text{Mn}, \text{Al})_{11.5-12}\text{O}_{18-19.5}$  has been measured under UV 254nm excitation. The spectral energy distribution of the  $\text{Mn}^{2+}$  emission is shown. The presence of divalent manganese suppressed the 454nm peak which exists in  $\text{CeAl}_{11}\text{O}_{18}$  without  $\text{Mn}^{2+}$  incorporation and gives a second peak at 520nm. With increasing divalent manganese content the phosphor emission goes from blue green to green. (Edited author abstract) 3 refs. In Chinese.

Anon (Baotou Rare Earth Research Inst, China). *Xi You Jin Shu* v 5 n 2 May 1986 p 86-90.

**078123 INFLUENCE OF GRINDING AND BAKING PROCESSES ON THE LUMINESCENT PROPERTIES OF ZINC CADMIUM SULFIDE PHOSPHORS FOR VACUUM FLUORESCENT DISPLAYS.** The surfaces of  $\text{Zn}_{0.25}\text{Cd}_{0.75}\text{S}:\text{Ag}, \text{Cl}$  phosphors

added with  $\text{In}_2\text{O}_3$  for vacuum fluorescent displays (VFD's) have been studied by x-ray diffraction, SEM, and Auger electron spectroscopy with emphasis on the effect of the grinding and baking processes upon nonuniform strain, decomposition, and oxidation. It is found that these phenomena affect the properties of low voltage cathodoluminescence used for VFD's. (Author abstract) 4 refs.

Itoh, Shigeo (Futaba Corp, Mobara, Jpn); Tonegawa, Takeshi; Pykosz, Thomas L.; Morimoto, Kiyoshi; Kukimoto, Hiroshi. *J Electrochem Soc* v 134 n 12 Dec 1987 p 3178-3181.

**078124 REGENERATED THERMOLUMINESCENCE AS A FUNCTION OF IRRADIATION TEMPERATURE.** The regenerated thermoluminescence (R-TL) is thermoluminescence when the phosphor is reheated after a regeneration time from and in the absence of irradiation. The phenomenon is more easily observed when the phosphors are heated before the first heating. The R-TL spectra, to  $T_m$ , consists of a continuum and well separated peaks.  $T_m$  is the maximum temperature of the first heating which quenches all peaks existing up to  $T_m$ . The authors investigated the R-TL in  $\text{LiF}$  (TLD-100),  $\text{F}_2\text{:Dy}$  (TLD-200) as a function of irradiation dose. 15 refs.

Kitis, G. (Univ of Thessaloniki, Thessaloniki, Greece); Charalambous, St. *Phys Status Solidi A* v 106 n 2 Feb 1988 p K175-K179.

**078125 SOME PECULIARITIES OF PHOTO-TRANSFER THERMOLUMINESCENCE IN  $\text{LiF}$ -TLD 100.**  $\text{LiF}$ -TLD 100 subjected to high exposure, annealed at 350 °C for 15 min, and then exposed to UV light exhibits thermoluminescence. This is known as photo-transfer thermoluminescence (PTTL) and is attributed to the transfer of charges from peak X1 traps, the only known survivors following a post-irradiation thermal anneal, to the shallower traps. Several results which cannot be explained by this simple model are presented. It is shown that peak XII traps play only a catalytic role in PTTL and actual transfer proceeds from some centers which have not been directly studied so far. (Author abstract) 21 refs.

Bhasin, B.D. (BARC, Bombay, India); Kathuria, S.P.; Moharil, S.V. *Phys Status Solidi A* v 106 n 1 Mar 1988 p 271-276.

**078126 ELECTROLUMINESCENCE OF  $\text{ZnS:Pb}$ ,  $\text{Cu}$ ,  $\text{Br}$  PHOSPHORS.** Some new data on  $\text{ZnS:Pb}$ ,  $\text{Cu}$ ,  $\text{Br}$  electroluminescent phosphors are presented. They show that the brightness could be increased and the initial instability could disappear almost completely by changes in the synthesis conditions and by making an appropriate solid state electroluminescent cell. The function of the lead impurity in the composition is to participate in the formation of a second phase of  $\text{PbS}$  which is more conducting than the  $\text{ZnS}$  phase. The  $\text{PbS}$  is more stable under ordinary atmospheric conditions compared to  $\text{Cu}_2\text{S}$ . That is probably the reason for the low aging rate of the blue emitting  $\text{ZnS:Pb}$ ,  $\text{Cu}$ ,  $\text{Br}$  electroluminescent phosphors. 4 refs.

Pakeva, S. (Univ of Sofia, Sofia, Bulg); Dafinova, R. *Phys Status Solidi A* v 106 n 1 Mar 1988 p K97-K100.

**078127 THERMOLUMINESCENCE IN SYNTHETIC LANGBEINITE.** The synthetic langbeinite  $\text{K}_2\text{Mg}_2(\text{SO}_4)_3$  doped with Sm is an efficient phosphor. In contrast to several other sulphate phosphors such as  $\text{CaSO}_4:\text{Dy}$ , the sulphate developed a visible colour upon irradiation. This note reports reflectance spectra, monochromatic glow curves, and TL emission spectra which provide an insight into the basic mechanism of thermoluminescence in this material. 4 refs.

Deshmukh, B.T. (Nagpur Univ, Nagpur, India); Bodade, S.V.; Moharil, S.V. *Phys Status Solidi A* v 106 n 1 Mar 1988 p K107-K111.

**078128 DOSIMETRIC PROPERTIES OF  $\text{KCl:Eu}$ .**  $\text{Eu}^{2+}$  ions change their valence state during the irradiation process as a consequence of the capture of either

electrons or holes. A strong emission in the blue region of the electromagnetic spectrum is produced when the irradiated specimens are heated from about room temperature up to 600 K. These results suggest that the europium-doped alkali halides may be good candidates for use in dosimetric applications because some of the characteristics which one tries to find in a solid state dosimeter are: (a) high thermoluminescence efficiency; (b) TL-spectrum of wavelengths in the wavelength region (400 to 500nm) in which commercial photodetectors respond well; and (c) low cost and easy availability. In order to achieve a better insight into this possibility, the dosimetric characteristics of the  $\text{KCl:Eu}$  phosphor material have been investigated. 13 refs.

Camacho, A.Q. (Univ Autonoma Metropolitana-Iztapalapa, Mex); Munoz, G.H.; Rubio J.O.; Garcia, J.M.; Murrieta, H.S.; Hernandez, J.A. *J Mater Sci Lett* v 7 n 5 May 1988 p 437-440.

**078129 TEMPERATURE DEPENDENT STUDIES OF CATHODOLUMINESCENCE OF GREEN BAND OF  $\text{ZnO}$  CRYSTALS.** Most of the work on cathode ray excitations of  $\text{ZnO}$  phosphors has been concentrated on low voltage excitations. The present paper reports cathodoluminescence studies of green band of  $\text{ZnO}$  crystals under high energy (40 keV) of excitation for the temperature range 4.2 to 300 K. These results enhance the utility of the model proposed by S. Bhushan et al. for the green band of  $\text{ZnO}$ . The crystals used in the present investigation have been prepared by the hydrothermal method. The excitation energy and the beam current of the cathode rays were 40 keV and 0.005  $\mu\text{A}$ , respectively. 22 refs.

## Performance

**078131 IMPROVED TERBIUM-ACTIVATED SINGLE-CRYSTAL PHOSPHOR FOR HEAD UP DISPLAY CATHODE RAY TUBE.** We report a new efficient  $\text{Ga}^{3+}$  substituted single-crystal phosphor  $\text{Y}_{3-x-y}\text{ Tb}_x\text{Lu}_y\text{Al}_5-w\text{Ga}_w\text{O}_{12}$  grown epitaxially on a  $\text{Y}_3\text{Al}_5\text{O}_{12}$  substrate. Gallium substitutions up to  $w \approx 2$  were made with y approximately 1.4w. The total light output was measured under electron beam excitation, and we observed a 35% increase in the light output at high power density excitation over that achievable with the best  $\text{Y}_{3-x}\text{ Tb}_x\text{Al}_5\text{O}_{12}$  films. The phosphor composition optimization with respect to  $\text{Tb}^{3+}$  and  $\text{Ga}^{3+}$  concentrations is reported. Our results are compared with literature data on similar garnet compounds prepared in powder form, or as bulk grown crystals, and films grown by liquid phase epitaxy. (Author abstract) 11 refs.

## Physical Properties

**078133 PHOTOLUMINESCENCE SPECTRA AND VIBRATIONAL STRUCTURES OF THE  $\text{SrS}:\text{Ce}^{3+}$  AND  $\text{SrSe}:\text{Ce}^{3+}$  PHOSPHORS.** The details of photoluminescence and excitation spectra of powder phosphors were obtained at various temperatures between 6 and 300 K. At 300 K, two emission bands originating from the  $^2T_{2g}(5d) \rightarrow ^2F_{7/2}$ ,  $^2F_{5/2}(4f)$  transitions are observed at 480 and 535 nm for  $\text{SrS}:\text{Ce}^{3+}$  and at 470 and 527 nm for  $\text{SrSe}:\text{Ce}^{3+}$ , respectively. In the excitation spectra, bands corresponding to the  $^2F_{5/2}(4f) \rightarrow ^2T_{2g}(5d)$  transition are observed at 433 ( $\text{SrS}:\text{Ce}^{3+}$ ) and 430 nm ( $\text{SrSe}:\text{Ce}^{3+}$ ), and plateaus due to the fundamental absorption of the host crystals in higher energy region. The vibrational structures on the emission and excitation bands are analyzed by the use of energy matrices in order to determine the coupling constant of spin-orbit interaction  $\zeta$  and the crystal field parameters  $V_4^{(0)}$ ,  $V_6^{(0)}$  for the 4f orbit. (Author abstract) 9 refs.

## Processing

**078134 EFFECT OF PREPARATION METHOD ON THERMOLUMINESCENCE IN  $\text{CaS}:\text{Ce}$ .** The work reported here is part of a systematic study of host lattice defects in  $\text{CaS}$ .  $\text{CaS}$  phosphors doped with cerium have been prepared by the reduction of sulphates in  $\text{H}_2/\text{H}_2\text{S}$  at 1020°C for 2 h. These samples were refired at 1020°C with  $\text{Na}_2\text{CO}_3/\text{S}$ ,  $\text{CaF}_2$  or  $\text{NH}_4\text{Cl}$  added as fluxing agents. Phase purity was monitored by X-ray diffractometry. Thermoluminescence spectra have been measured on both fluxed and unfluxed samples in the range 80 to 450 K. Five glow peaks were observed. One may be related to sulphur vacancies, another to calcium vacancies and a third to the presence of transition metal impurities in the lattice. With increasing cerium concentration the TL emissions increase and also broaden. (Author abstract) 9 refs.

## Production

**078135 GROWTH PARAMETER OPTIMIZATION AND  $\text{Tb}^{3+}$  SENSITIZATION OF  $\text{Ce}^{3+}$  ACTIVATED  $\text{Y}_3\text{Al}_5\text{O}_{12}$  PHOSPHOR.** Cerium activated  $\text{Y}_3\text{Al}_5\text{O}_{12}$  has been grown by liquid phase epitaxy (LPE) from a  $\text{PbO}-\text{B}_2\text{O}_3$  flux. Cathodoluminescence measurements of  $(\text{Y}_{3-x}\text{Ce}_x)\text{Al}_5\text{O}_{12}$  show an internal efficiency of 6.5% at the film composition and optimal growth conditions. Numerous lanthanide ions were studied in a series of LPE film growths to evaluate each as a sensitizer of  $\text{Ce}^{3+}$  emission in  $\text{Y}_3\text{Al}_5\text{O}_{12}$  hosts.  $\text{Tb}^{3+}$  additions increased the cathodoluminescence by 70% to yield an internal efficiency of 11%. The conditions of LPE growth which provide maximum performance in  $(\text{Y}_{3-x}\text{Ce}_x)\text{Al}_5\text{O}_{12}$  and in  $(\text{Y}_{3-x-y}\text{Ce}_x\text{Tb}_y)\text{Al}_5\text{O}_{12}$  are discussed. Consideration is given to reagent purity of the solute and flux components. The luminescence of  $(\text{Y}_{3-x-y}\text{Ce}_x\text{Tb}_y)\text{Al}_5\text{O}_{12}$  was analyzed by photoluminescence and time-resolved cathodoluminescence. (Edited author abstract) 18 refs.

## Research

**078136 EFFECT OF ELECTRON-HOLE CORRELATIONS ON THE LUMINESCENCE OF CRYSTALLINE PHOSPHOR WITH TRAPS.** A model of a crystalline phosphor with traps with two channels of electron-hole recombination (direct and through the luminescence center) is examined. The dependence of the quantum output of luminescence of one of the channels on the dispersion length of the electron and hole during the hot relaxation stage is established. The dependence of the quantum output of luminescence on the energy of the incident photons, the intensity of the incident light, and its temperature is constructed. (Author abstract) 6 refs.

Vasil'ev, A.N.; Mikhailin, V.V.; Ovchinnikova, I.V. *Moscow Univ Phys Bull* v 42 n 3 1987 p 57-61.

**078137 TERBIUM-EUROPIUM ACTIVATED SILICATES.** Efficient, 254 nm excited emission has been realized for both trivalent terbium and europium in a series of calcium magnesium silicates. The existence of significant emission intensities of both species is associated with excitation of Eu by Tb emission in the ultraviolet and at 485 nm. This indicates that cross-relaxation between terbium and europium energy levels is the responsible energy transfer mechanism. (Edited author abstract) 8 refs.

## Service Life

**078138 FLUORESCENCE LIFETIME OF 5-(4-CARBOXYPHENYL)-10,15, 20-TRITOLYLPORPHYRIN IN A MIXED LANGMUIR-BLODGETT FILM WITH DIOLEOYLPHOSPHATIDYLCHOLINE. A PROPOSED STANDARD.** Time-resolved fluorescence lifetime measurements of 5-(4-carboxyphenyl)-10,15,20-tritolylporphyrin (TTPa) with dioleoylphosphatidylcholine (DOPC) in mixed Langmuir-Blodgett (LB) films on quartz slides were performed at two different laboratories. TTPa in the mixed LB film exhibited a simpler and longer decay profile than did a pure TTPa monolayer. At a DOPC/TTPa molar ratio of 50:1, the decay consisted primarily of one lifetime of  $10.7 \pm 0.2$  ns. This mixed LB film is being offered as a standard for time-resolved fluorescence lifetime measurements of LB films. Simplification and lengthening of the lifetime were attributed to reduction of TTPa aggregate formation in the film. This effect is also seen in fluorescence and absorption spectra. The fluorescence lifetime of the standard system at the air-water interface was also measured and found to be essentially the same as that of the LB film. (Author abstract) 14 refs.

## Spectroscopic Analysis

**078139 ENERGY TRANSFER BETWEEN  $\text{Ce}^{3+}$  AND  $\text{Tb}^{3+}$  IONS IN  $\text{LaOBr}:\text{Ce}^{3+}$ ,  $\text{Tb}^{3+}$ .** The energy transfer between  $\text{Ce}^{3+}$  and  $\text{Tb}^{3+}$  ions in  $\text{LaOBr}:\text{Ce}^{3+}$ ,  $\text{Tb}^{3+}$  was systematically studied. The emission spectra of  $\text{Ce}^{3+}$  and  $\text{Tb}^{3+}$  in  $\text{LaOBr}:\text{Ce}^{3+}$ ,  $\text{Tb}^{3+}$  have been measured with excitation at 355 and 250 nm. At the same time, the fluorescence lifetime and time-resolved spectra in nanosecond scale, for a series of samples doped with different concentrations, were measured. The temperature dependence of energy transfer efficiency  $\eta_{\text{SA}}$  and probability of energy transfer  $P_{\text{SA}}$  from  $\text{Ce}^{3+}$  to  $\text{Tb}^{3+}$  was studied. It was found that energy is transferred, not only from  $\text{Ce}^{3+}$  to  $\text{Tb}^{3+}$ , but also from  $\text{T}^{3+}$  to  $\text{Ce}^{3+}$ . A model of energy transfer is proposed. (Author abstract) 7 refs.

**078146 ADSORPTION MECHANISM OF PHOSPHORUS ON ALUMINA.** The effect of phosphorus on the acidity and physical properties of a support of  $\gamma$ -alumina was studied, as a preliminary stage to understanding its role as an additive in hydrotreatment catalysts. The results showed that phosphorus was adsorbed on alumina following a Langmuir-type mechanism, in which a phosphate ion monolayer was formed at the surface. Equilibrium was strongly displaced towards adsorption. These results were verified using X-ray photoelectron spectroscopy. Phosphorus modified not only the acidity but also the physical properties of the alumina. From the experimental results obtained, an adsorption mechanism of phosphorus on alumina could be established. (Author abstract). 13 Refs.

**Phase Transitions**

**078148 STABILITY OF THE SIMPLE CUBIC PHASE OF PHOSPHORUS.** The transition from the rhombohedral phase to the simple cubic phase of phosphorus under pressure is studied within the local density-functional formalism with use of the norm-conserving pseudopotential. The calculated transition pressure is 15.8 GPa, which is in good agreement with the measured value, 10 GPa. The bonding in the simple cubic phase is shown to be structure under low pressures is understood

by a Peierls' instability, which is just the same as the case of arsenic. It is also shown that the mixing of atomic 3d-orbitals in the occupied states is important for stabilizing the simple cubic structure under high pressure. (Author abstract) 14 refs.

**Physical Properties**

**078149 INTERPLANAR FORCES OF BLACK PHOSPHORUS CAUSED BY ELECTRON-LATTICE INTERACTION.** The generalized electronic susceptibility of a narrow gap semiconductor, black phosphorus, is calculated by using electron-lattice coupling constants derived microscopically on the basis of tight-binding calculations of the electronic band structure. Interplanar forces along the [100] direction caused by the electron-lattice interaction are evaluated from the obtained generalized electronic susceptibility. Reflecting the narrow gap the interplanar forces take significant values even for far neighboring planes. Considerable decrease of the energy gap induced by pressure gives rise to characteristic pressure dependences of the interplanar forces, which lead to qualitative explanation of the observed pressure dependences of the phonon dispersion curves. (Edited author abstract) 29 refs.

**Production** See Also POWDERS—Compaction.

**078150 ELEKTROKINETIC POTENTIAL OF PHOSPHORUS DISPERSION IN SLIMES OF PHOSPHORUS PRODUCTION.** In order to develop and improve the method of yellow phosphorus isolation from the slime by applying an external electric field, it is necessary to know the sign of the charge of the dispersed phosphorus in the slime as well as the factors affecting it. Determination of the conditions in which the phosphorus dispersion loses its charge is essential. To solve these problems, in this work we measured the electrokinetic potentials of the phosphorus dispersion right in the salt-containing water taken from the slime collector in the neutralization section. The results obtained give enough information for evaluation of the electrochemical behavior of phosphorus dispersion, which is a constituent of the phosphorus slime, in practicable conditions and for ascertaining the technological parameters of the process of isolation of the phosphorus dispersion from the mineral part of the slime in an external electric field. Comparing the data obtained, it can be concluded that orthophosphates are adsorbed in concentrated solutions, i.e., in salt-containing slime water, mainly at low pH values (2-3). In more diluted solutions, i.e., at a reduced ionic strength, orthophosphates are adsorbed at higher pH values (4-5). Thus phosphorus dispersion in slimes of phosphorus production is negatively charged due to adsorption of ortho- and polyphosphates. At 60°C and pH 2-3 the potential-determining ions are desorbed and the phosphorus dispersion loses its charge. 9 refs.

**Spectroscopic Analysis**

**078151 DETERMINATION OF PHOSPHORUS DISTRIBUTION IN THE SILICON DIOXIDE/SILICON LAYER SYSTEM BY SECONDARY ION MASS SPECTROMETRY.** A measurement technique for quantitative distribution analysis of phosphorus in the layer system  $\text{SiO}_2/\text{Si}$  was developed. Oxygen primary ions and an increased oxygen pressure ( $5 \times 10^{-5}$  mbar) in the sample chamber were used for elimination of the matrix effect. Precise adjustment of the mass spectrometer during depth profiling with high mass resolution was controlled by a computer routine. Charging effects were compensated by flooding of the sample with electrons, optimized biasing of the accelerating potential of the secondary ions, and normalization to a reference signal. A detection limit of  $1 \times 10^{16}$  atoms  $\cdot \text{cm}^{-3}$  and an accuracy of  $\pm 30$  percent were obtained. (Edited author abstract). 22 refs.

**Chemical Reactions**

**078152 RADIOCHEMICAL ANALYSIS OF PHOSPHORUS EXCHANGE KINETICS BETWEEN SEDIMENTS AND WATER UNDER AEROBIC CONDITIONS.** Adsorption-desorption reactions of P by lake sediments, Lake Kasumigaura, Japan, were studied using radioisotope  $^{32}\text{P}$  inorganic phosphate. Exchange rates and amounts of exchangeable P in sediments were measured in aerobic sediments-water batch systems under different pH and P concentration conditions. Exchangeable P ranged from 6 to 43% of the total P in the indigenous sediments. Increasing pH induced P desorption from sediment. The relationship between the concentration in water and the amount of exchangeable P could be explained by the Langmuir equilibrium model. However, the Langmuir rate equation cannot describe the kinetics of whole exchange reactions. The adsorption-desorption reaction was composed of an exchange reaction and a slow adsorbed-reaction. The exchange reaction has two phases - very rapid reaction and a Langmuir-type reaction. (Author abstract) 16 refs.

## Magnetic Properties

**078157 (Fe,Co)-P THIN FILMS PREPARED WITH A REACTIVE EVAPORATION METHOD.** Magnetic properties of (Fe,Co)<sub>2</sub>P thin films prepared with the thermal-activated reactive evaporation method were investigated for recording media application. Above 300°C, metals (Fe,Co) and phosphorus react to form M<sub>2</sub>P. The coercive forces of these films had a maximum value of 1.3 kOe at 10% Co concentration, and the saturation magnetization increased with the increase in Co concentration. Annealing at 500°C for 30 min increased the coercive force of the films up to two times. The reproduced output from the isolated magnetization transitions of a (Fe,Co)-P-film rigid disk with a ring head showed waveforms of typical longitudinal recording. A recording density of 62 kfrpi at D<sub>50</sub> was attained with a disk medium of about an 800-angstrom-thick layer. 16 refs.

## Molecular Structure

**078158 IR AND/OR NMR SPECTRA-STRUCTURE CORRELATIONS FOR ORGANOPHOSPHORUS COMPOUNDS.** This study is an attempt to develop correlations between IR and/or NMR phosphorus-31 data with molecular structure. It is found that increased branching on the  $\alpha$ -C-P carbon atom causes  $\delta(^{31}\text{P})$  to occur at increasing higher frequency in a systematic manner. The  $\delta(^{31}\text{P})$  frequency increases with increased electron release of the alkyl groups. Correlations exist between  $\delta(^{31}\text{P})$  and  $\delta(\text{N})$  for corresponding alkyl analogs of RPH<sub>2</sub> vs. RNH<sub>2</sub>, (R)<sub>2</sub>PH vs. (R)<sub>2</sub>NH, and (R)<sub>3</sub>P vs. (R)<sub>3</sub>N. The  $\nu(\text{P}=\text{O})$  frequency and  $\delta(^{31}\text{P})$  decrease in frequency with increased branching on the  $\alpha$ -C-O-P carbon atoms for P(=O)(OR) analogs, and a correlation exists between  $\nu(\text{P}=\text{O})$  and  $\delta(^{31}\text{P})$ . 9 Refs.

## Polymerization

**078159 CYCLIC COMPOUNDS CONTAINING PHOSPHORUS ATOMS IN THE RING.** This paper describes the ring-opening polymerization of cyclic phosphorus-containing monomers. Polymers discussed in this paper are derived from cyclic monomers with the phosphorus atom at two different levels of oxidation, namely penta- and trivalent. Structurally these compounds can be penta-, tetra- or tri-coordinated with direct bonding of phosphorus with oxygen or carbon atoms. Some inorganic monomers and polymers are also presented, mostly based on the 6-membered cyclic phosphazenes. Monomers are discussed first, including general methods of preparation and some properties (e.g. stereochemistry), and then the conditions of polymerization, thermodynamics, kinetics and mechanism of polymerization. 265 refs.

Lapienis, G. (Polish Acad of Sciences, Lodz, Pol); Penczek, S. *Ring-Opening Polym* v 2. Publ by Elsevier Applied Science Publ, London, Engl and New York, NY, USA, 1984 p 919-1053.

## Spectroscopic Analysis

**078160 NMR STUDIES OF THE P<sub>2</sub>O<sub>5</sub>-SiO<sub>2</sub> SOL AND GEL CHEMISTRY.** Two phosphosilicate sols were studied by <sup>1</sup>H, <sup>13</sup>C and <sup>31</sup>P NMR, and their gels were studied by <sup>31</sup>P NMR. The <sup>1</sup>H and <sup>13</sup>C NMR spectra show that the hydrolysis of Si(OCH<sub>2</sub>CH<sub>3</sub>)<sub>4</sub> is much faster than that of PO(OCH<sub>2</sub>CH<sub>3</sub>)<sub>3</sub> in alcoholic solvent. The hydrolysis of PO(OCH<sub>2</sub>CH<sub>3</sub>)<sub>3</sub> is slow as its content increases in the sol while the other conditions are unchanged. The <sup>31</sup>P NMR spectra show that there are no P-O-P and P-O-Si bonds in the sols 9 h after the beginning of the reaction, but these bonds were found in the gels. (Author abstract) 9 Refs.

## Structure

**078161 THERMAL NEUTRON DIFFRACTION STUDY OF LIQUID PHOSPHOR TRIBROMIDE UNDER ISOBARIC CONDITION AT 295 K.** The intermolecular scattering function of liquid phosphorus tribromide is studied under isobaric condition at 295 K in a range of the scattering parameter,  $5.0 < k[\text{nm}^{-1}] < 60$ . A striking resemblance is found with results reported on liquid SbCl<sub>3</sub>. The intermolecular scattering function is tabulated. The liquid structure of PBr<sub>3</sub> can not be described very well by the RISM, similar to SbCl<sub>3</sub>. (Edited author abstract) 10 Refs.

## Synthesis

**078162 STRUCTURAL STUDIES OF SOME NEW LAMELLAR MAGNESIUM, MANGANESE AND CALCIUM PHOSPHONATES.** Layered phosphonate salts of divalent metal ions (Mg, Ca and Mn) are prepared by combining solutions of soluble metal salts and alkyl- or arylphosphonic acids. The M(O<sub>3</sub>PC<sub>6</sub>H<sub>5</sub>)-H<sub>2</sub>O compounds show good thermal stability losing lattice water at 250-300°C without further decomposition below 550°C. Compounds derived from alkylphosphonic acids decompose at lower temperatures. The structure consists of roughly coplanar layers of metal atoms coordinated by phenylphosphonate groups above and below. Each metal atom is coordinated by five phosphonate oxygens and one lattice water molecule. These compounds are interesting as potential microporous catalysts, sorbents and ion exchangers. 17 refs.

**PHOTOCATHODES** See Also ELECTRON TUBES, IMAGE INTENSIFIER; PHOTODETECTORS; PHOTOEMISSIVE DEVICES.

**078163 LIQUID AND SOLID ORGANIC PHOTOCATHODES.** We have investigated the possibility of creating photocathodes for gaseous detectors with a high sensitivity in the photon spectral region between 105 and 300 nm. Metal cathodes covered with liquid or solid organic layers, such as tetrakis(dimethylamine)ethylene (TMAE) and tetramethyl-p-phenylenediamine (TMPD) and solutions of these substances, were studied using two different experimental setups: a proportional wire chamber and a single-wire counter. Three effects were observed. (Edited author abstract) 34 refs.

## Applications

**078164 APPLICATION OF FEU WITH SEMITRANSSPARENT NEGATIVE-ELECTRON-AFFINITY PHOTOCATHODES FOR SCINTILLATION DETECTORS AND LIGHTGUIDES.** The development of scintillation blocks for detecting  $\gamma$  radiation with an energy resolution of 4-7% is very important for the analysis of the elemental composition of rocks and ores. In this connection, together with improving the quality of the scintillation detectors, it is also necessary to improve the characteristic amplitude resolution of FEU. This is especially important for the group of scintillation detectors whose emission spectra lie in the range 500-900 nm. The use of semitransparent photocathodes of a new class with structures with negative electron affinity (NEA-photocathodes) are discussed. This opens up the possibility of raising substantially (by a factor of 5-10) the sensitivity of the photocathode and therefore reducing significantly the characteristic amplitude resolution of FEU. Such FEU are called quantocons. 4 refs.

## Efficiency

**078165 PHOTOACOUSTIC IN SITU MEASUREMENT OF QUANTUM EFFICIENCY FOR PHOTOELECTROCHEMICAL EVOLUTION OF HYDROGEN ON p-INDIUM PHOSPHIDE.** It is known that InP functions as an efficient semiconductor photoelectrode in a photoelectrochemical cell. The direct band gap of 1.35 eV makes it a very suitable material for photovoltaic solar energy conversion. In this paper, the authors report the results of measurements of optical behavior with respect to p-InP and the 'in situ' quantum efficiency for the photoelectrochemical evolution of hydrogen on p-InP and Pt-plated p-InP photocathodes by photoacous-

tic spectroscopy, using a piezoelectric transducer as the detector. 11 refs.

**078167 PULSED PHOTOCURRENTS FROM LANTHANUM HEXABORIDE CATHODES IN THE ns REGIME.** Photocathode emission investigation represents an essential part in developing new rf sources and new bunched electron guns. In order to determine the photoemissivity of different materials with work functions which can be easily lowered, we studied lanthanum hexaboride ( $\text{LaB}_6$ ) as a first step. The results of measurements with a nanosecond Nd-YAG laser, using wavelengths from 1064 to 355 nm, show that pulsed photocurrent densities can reach  $7 \text{ kA/cm}^2$ . Quantum yields evolved from  $10^{-7}$  to  $10^{-3}$  with the lowering of the work function when cleaning the surface under laser exposition. The results also show that with the use of high density photon beams of approx.  $45 \text{ J/cm}^2$ , lanthanum desorption occurs at the surface. Suggestions are given for a cure of this desorption problem. (Author abstract) 5 refs.

## Service Life

**078168 TUNGSTEN HAIRPIN CATHODES WITH LONGER LIFETIMES.** The lifetime of tungsten hairpin cathodes is shorter than would be theoretically possible, if their maximum temperature were always in the emission centre. The publications dealing with this problem only explain why the maximum temperature is not at the vertex, but offer no solution on how to overcome the resulting asymmetry and the instability of the temperature distribution. An analysis of the possible reasons for this phenomenon indicated possibilities of how this could be corrected. This paper will discuss how raising the temperature gradient near the vertex can increase the lifetime of the cathode. This places the maximum temperature very close to or directly in the emission centre. The thickness of the wire and the temperature at this point will then determine the lifetime, which becomes therefore many times longer. (Author abstract) 5 refs.

**078170 LAWS OF COLORING OF PHOTOCHROMIC SOLUTIONS USED IN EXPERIMENTAL HYDRODYNAMICS.** It is known that the introduction of small quantities of photochromic compounds into a liquid flow makes it possible to obtain colored tracks in the solution by directional irradiation at a certain wavelength. The authors study the photochromic characteristics of an aqueous solution of spiropyran 11. We determined the length of the colored track in relation to the energy of the activating laser radiation and the concentration of photochromic substance in the solvent. They established the range of concentration of the photochromic substance and of other parameters necessary to reliably record a colored track. 11 refs.

## Mathematical Models

**078173 MATHEMATICAL MODELING OF PHOTOCONDUCTOR TRANSIENT RESPONSE.** A photoconductor device model that is based on time-dependent convective/diffusive continuity and transport equations is presented. Electron and hole trapping on deep-level impurities is accounted for by trapping-kinetics rate equations. The coupling between carrier drift and electric field is expressed by Poisson's equation. The system of model equations is solved numerically with boundary conditions that represent ideal ohmic contacts. Computed

results are presented for different photoconductor lengths and bias voltages with spatially uniform, rectangular light-pulse excitation. Material parameters appropriate for iron-doped indium phosphide are used. 10 refs.

**Optical Properties** See SEMICONDUCTING ZINC COMPOUNDS—Spectrum Analysis.

## Switching

**078174 TRANSPORT CORRELATION COEFFICIENTS AND PHOTOCONDUCTIVE SWITCHING.** The use of a retarded Langevin equation for the development of a simple model of a photoconductive switch is described. This model allows the accurate determination of carrier transport transients in the switch provided that certain commonly made assumptions concerning spatial homogeneity remain valid and an appropriate optical pulse energy and wavelength are chosen. The model utilizes velocity autocorrelation functions which could be estimated by Monte Carlo techniques or potentially measured by applying the model to experimental data. The validity of the model is demonstrated for wavelengths in which carriers are generated somewhat below the threshold for intervalley scattering. A mechanism by which an applied field can actually delay the initial rise in a photocurrent in a subpicosecond photoconductive experiment is described. (Edited author abstract) 9 refs.

**PHOTOCONDUCTING MATERIALS** See Also GLASS, METALLIC—Synthesis; IMAGE SENSORS—Contacts; POLYMERS—Electric Properties.

**078175 NEW APPARATUS FOR MEASURING PHOTOCONDUCTIVE CHARACTERISTICS LINKED TO VACUUM EVAPORATION EQUIPMENT.** The high sensitivity of photoconductive film (called target) in the pick-up tube of the high definition TV (HDTV) camera is sought. A mechanism to move a target in vacuum has been designed, and an apparatus for measuring target characteristics, linked to a vacuum evaporation equipment, has been developed. This apparatus can be used to measure the characteristics of evaporated target immediately, without exposure to the atmosphere. Since all the processes from evaporation to measurement are accomplished continuously in a vacuum, measurement efficiency can be improved. Another advantage is that materials which oxidize easily in the atmosphere can be tested, and changes in the characteristics of a target in the process of evaporation can also be measured. This paper describes the configuration of the new apparatus, and gives examples of the measurement of target characteristics as an application. 1 ref.

**078176 MEASUREMENT OF PHOTOCARRIER INJECTION EFFICIENCIES AT THE INTERFACE IN DOUBLE LAYERED ORGANIC PHOTOCONDUCTORS.** Photocarrier injection efficiencies from the carrier generation layer into the transport layer in double-layered photoconductors were measured by using a photoacoustic technique. Photoinjection efficiencies were derived by measuring the decrease in photoacoustic signal when an electric field was applied to the samples. A linear relationship was observed between the logarithm of the photoinjection efficiencies and the square root of the applied electric field. Photocarrier injection efficiencies are

limited by a barrier between the carrier generation layer and the carrier transport layer. (Author abstract) 9 refs.

**078177 TIME-DEPENDENT PHOTOCONDUCTIVITY IN  $\text{CdIn}_2\text{S}_4$ .** To investigate the photoresponse due to defect levels in  $\text{CdIn}_2\text{S}_4$ , the measurement of photocurrent was carried out as a function of light intensity and time. It was found that the photocurrent showed a strong dependence both on time and light intensity, indicating the existence of photoactive levels at the top of the valence bands. The  $\text{CdIn}_2\text{S}_4$  single crystals were grown from a melt of the stoichiometric composition of six-nine purity elements with 0.25% excess sulfur. The resistivity of the crystal exceeded more than  $5 \text{ M}\Omega \cdot \text{cm}$  at room temperature. Chopped light (80 Hz) was incident and focused on the  $1 \times 1 \text{ mm}^2$  area in the center of the  $3 \times 7 \text{ mm}^2$  sample surface, and the a.c. amplitude of photocurrent was measured using usual synchronous detection techniques at room temperature. 7 refs.

## Electrochemistry

**078180 PHOTOELECTROCHEMICAL SPECTRAL RESPONSE OF AIR-SINTERED PHOTOCONDUCTING  $\text{CdS}$  IN RELATION TO SURFACE IMPURITY PHASE(S).** We explored the possibility of employing photoelectrical (PEC) measurement techniques in order to study the relevant photoeffects in air-sintered pellets of CdS, principally, because such measurement techniques necessarily deal with a solid (electrode)-liquid (electrolyte) junction in contrast to only solid state as in the case of photoconductivity measurement techniques. During the course of this investigation, we dealt with PEC spectral response studies on such air-sintered pellets of  $\text{CdS}:\text{Cu}:\text{Cl}$ . Although PEC spectral response studies on air-sintered pellets of  $\text{CdS}:\text{Cu}:\text{Cl}$  are interesting, the purpose of characterizing impurity phase(s) photoelectrochemically in order to understand the relevant photoeffects at  $\text{CdS}:\text{Cu}:\text{Cl}$  has not been fully served, because of chemical reaction between the impurity phase(s) and an electrolyte [i.e.  $\text{Na}_2\text{S}$ ]. 9 refs.

## Synthesis

**078182 PHOTOCONDUCTION OF RAPIDLY QUENCHED FILMS IN THE  $\text{PbO-TiO}_2$  SYSTEM.**  $\text{PbO-TiO}_2$  films were prepared by a rapid quenching technique, using twin-roller type equipment. The quenched films, containing from 10 to 30 mol%  $\text{TiO}_2$ , precipitated tetragonal  $\text{PbO}$  solid solution as a single phase.  $\text{PbTiO}_3$  crystals precipitated from a melt with an equimolar composition of  $\text{PbO}$  and  $\text{TiO}_2$  had a denser structure and a lower tetragonality compared to those obtained by solid-phase reaction. In films containing 60 mol%  $\text{TiO}_2$  or more, the formation of an amorphous phase was predominant. Both crystalline films and amorphous  $\text{PbTiO}_3$  films showed photoconductivity. (Edited author abstract) 16 refs.

Sekiya, T. (Government Industrial Research Inst, Nagoya, Jpn); Futakuchi, T.; Tsuzuki, A.; Kawakami, S.; Torii, Y. *Mater Res Bull* v 22 n 11 Nov 1987 p 1555-1561.

## Temperature Effects

**078183 TEMPERATURE DEPENDENCE OF AMBIPOLAR MOBILITY FOR A 0.1 eV n-TYPE  $\text{HgCdTe}$  PHOTOCONDUCTOR.** Temperature dependence of ambipolar mobility for a 0.1 eV n-type  $\text{HgCdTe}$  photoconductor was derived in the 10-100 K temperature range, from experimental results on excess minority carrier lifetime and ratio of responsivity at low electric field to that at high field. It was found that the ambipolar mobility decreases exponentially above 60 K, while it has a constant value between 30 and 60 K. The mobility behavior above 60 K indicates that a dominant scattering mechanism is a polar optical phonon scattering with approximately 16 meV phonon energy. The results will be useful for design of SPRITE detectors. (Author abstract) 14 refs.

Oda, Naoki (NEC Corp, Kawasaki, Jpn). *Infrared Phys* v 28 n 2 Mar 1988 p 91-95.

## Testing

**078184 FIELD DEPENDENCE OF OPTICAL BAND GAP IN MANGANESE PHOSPHATE GLASSES.** Photoconduction measurements are made in the spectral energy range 1.5-6.2 eV on a manganese phosphate glass with composition 40 mol%  $\text{MnO}$  and 60 mol%  $\text{P}_2\text{O}_5$ . The values of energy band gap are deduced by extrapolation of the linear region of the spectral dependence curves, obtained at various applied fields. These values decrease slowly with increasing field, and a band gap value of 5.07 eV is derived for zero field. The results can be explained in terms of energy bands for

amorphous materials, and are similar to those obtained for other metal phosphate glasses. (Author abstract) 13 refs.

## Transport Properties

**078186 PULSED LASER INDUCED PHOTOCONDUCTIVITY IN  $\text{ZnS}$  - PART I.** The photoconductivity spectrum of  $\text{ZnS}$  has been recorded using dye lasers, and the nonlinearity of the lux-ampere characteristics has been studied at the band edge frequency. The presence of space charge effect in the crystal has been confirmed by studying the current-voltage characteristics. The charge vs. intensity characteristics using high power pulsed lasers (XeCl excimer laser, frequency doubled and fundamental Nd:YAG laser) indicate one, two and four photon photoconductivity processes in the crystal. The long-lasting controversy between the superlinear behavior of lux-ampere characteristics and the two photon photoconductivity of the V-C'-C type (V stands for valence band, C' for intermediate band and C for conduction band) has been resolved. (Edited author abstract) 22 refs.

**078188 PROCESSING A DIFFRACTION PATTERN WITH A CHARGE-COUPLED DEVICE PHOTODETECTOR.** The widespread use of charge-coupled device (CCD) photodetectors as contactless devices for measuring dimensions can be credited to several advantages of these detectors: a low supply voltage, a fast response, small dimensions, low weight, etc. In particular, CCD photodetectors hold promise in diffraction systems for measuring the parameters of microscopic objects from their Fraunhofer diffraction patterns. Despite the advantages of this new type of photodetector, its use in such systems can result in errors which are unjustifiably large. The purpose of the present study was to determine the reason for modulation of diffraction intensity distribution and to develop an algorithm for correcting the optical signal on the basis of a distortion-inversion method. 5 refs.

**078189 Pb<sub>2</sub>CrO<sub>5</sub> PHOTOVOLTAIC DEVICE FOR THE DETECTING LIGHT-BEAM POSITION.** A light position detector operating through a photovoltaic effect of a Pb<sub>2</sub>CrO<sub>5</sub> ceramic disk with a pair of Au planar electrodes is investigated. A fabrication technique and the basic characteristics of the photovoltaic device for position detection are described. A peak photovoltage is obtained around the edge of the electrode for an incident light beam. The incident light beam shape and the electrode pattern are important factors for obtaining a linear relation between the light-beam position and the output signal from the device. A device fabricated for detecting one-dimensional light position has a high position resolution of 0.5 μm and a good linearity of ±2 μm or less. A two-dimensional device can be fabricated in the same way as the one-dimensional device, except for the electrode

pattern. A method for two-dimensional light position detection using a Pb<sub>2</sub>CrO<sub>5</sub> photovoltaic cell is demonstrated for a green LED as a light source. (Author abstract) 5 refs.

**078190 LOW-PRESSURE ULTRAVIOLET PHOTON DETECTOR WITH TMAE GAS PHOTOCATHODE.** Results of the study of the properties of a low pressure multistep avalanche counter with TMAE (tetraakis(dimethylamine)ethylene) as the photosensitive gas are presented. The optimization of parameters is discussed. Absolute gas amplification, drift velocity and diffusion of drifting photoelectrons in a low pressure gas and the efficiency of single photoelectron detection are measured. The practical multihit capability and spatial resolution are explored in view of possible application in a Cherenkov ring imaging with multipad wedge-and-strip cathode readout with flash ADCs. The present limit in spatial resolution is due to diffusion of drifting electrons in a low-pressure gas. For applications where photons are detected in a high-rate background of charged particles, the low-pressure operation has many advantages over the

atmospheric pressure detectors. (Author abstract) 38 refs.

**078191 GATED WIRE PHOTODETECTOR FOR HIGH FLUX OPERATION.** A method of gating the wire gas discharge photodetector with electrical and fibre-optical readout is investigated. No restrictions due to positive space-charge effects have been revealed in the flux range up to  $5 \times 10^5$  p.h.e./mms per anode wire. Hodoscope photomultipliers are used for light detection at the fibre exits. (Author abstract) 11 refs.

**078192 POWER SPECTRAL DENSITY ESTIMATION OF LIGHT INTENSITY FLUCTUATIONS IN PHOTON COUNTING.** A light beam which has a constant amplitude and is incident on a photomultiplier cathode generates completely random current impulses. When the incident light intensity is fluctuating, the probability of generating current impulses is also fluctuating in time, and hence one will find current impulses obeying a compound Poisson process. The ratio of the variance to the average number of counts in successive time slots becomes larger than unity and dependent on the time slot width of the photon counting. The present paper gives a formula which reduces the shot noise level and derives the psd of the intensity fluctuations from the dependence of the variance-to-mean ratio on the time slot width. The limitation of this technique is discussed and the validity of the technique is demonstrated by computer simulation. (Author abstract) 5 refs.

**078193 OPTICAL PHOTODETECTION BY TRANSFORMATION OF PHOTOELECTRONS INTO SECONDARY WAVES.** A method has been developed whereby near-photon-counting performance can be achieved at high signal levels in gated optical systems of long coherence time. The method involves converting the received photoelectrons into single-frequency secondary waves. Linear performance has been demonstrated even when the photon-counting pulses greatly overlap. Furthermore, the effect of a non-stationary background may be taken into account simply as the square root of its intensity, without recourse to chopping at the signal overlap and in the background spectra. (Author abstract) 7 refs.

**078194 RAPPORT DES COEFFICIENTS D'IONISATION ET DE BRUIT DANS LES PHOTODETECTEURS A AVALANCHE Hg<sub>0.44</sub>Cd<sub>0.56</sub>Te λ = 1,6 μm.** [Relation Between Ionization and Noise Coefficients in Hg<sub>0.44</sub>Cd<sub>0.56</sub>Te Avalanche Photodetectors at λ = μm]. The purpose of this paper is the characterization of Hg<sub>1-x</sub>Cd<sub>x</sub>Te avalanche photodiode with  $x \approx 0.56$ ,  $E_g = 0.73$  eV and  $\Delta = 0.8$  eV. The difference with full equality  $\Delta = E_g$  is 0.07 eV, which is higher than 2kT. This characterization will give the experimental proof in the case where  $\Delta > E_g + 2kT$  that the ionization by impact process relative to spin-orbit resonance and Auger recombination are not involved. Also the electrons become the most ionizing carriers with an ionization energy of 1.1 E<sub>g</sub>. The value of the ratio  $k = \alpha/\beta$  is deduced from noise measurements,  $\alpha$  and  $\beta$  being respectively the electron and hole ionization coefficients. The value  $k$  is equal or higher than 4. This result shows that Hg<sub>0.44</sub>Cd<sub>0.56</sub>Te APD technology must be modified in order to initiate the multiplication by electrons and not by holes which is the case in this study. (Author abstract). 9 Refs. In French.

**078195 PHOTODETECTEURS POUR TRANSMISSIONS PAR FIBRE OPTIQUE A 1,3 μm - 1,55 μm : ETAT DE L'ART.** [Photodetectors for 1.3μm-1.55μm Fiber Optical Transmissions: State of the Art.]. In the optical fiber telecommunication systems, the emission and reception modules contain optoelectronic components such as laser diodes and photodiodes. Beside the laser whole task and complexity are obvious, the photodiode, the mechanism of which is quite straight-forward, becomes a sophisticated device when optimized for 1.3-1.55 μm fiber window. For photodetection, the photodiode is always associated to a preamplifier obtained from a transistor. For a given link, the performances of the receiver straightly depend on those of the photodiode and of the transistor. Different types of photodetectors are suitable for 1.3 μm and 1.5 μm transmissions. This paper surveys the different semiconductor materials and device structures encountered nowadays, pointing out the respective merits of each solution. Comparisons between photoreceivers outline the importance of matching the photodiode to the transistor, whether dealing with hybrid or monolithic circuits. (Author abstract). 7 Refs. In French.

**078197 BANDWIDTH MEASUREMENTS OF ULTRAHIGH-FREQUENCY OPTICAL DETECTORS USING THE INTERFEROMETRIC FM SIDEBAND TECHNIQUE.** A frequency-modulated semiconductor laser and an interferometer are used as a source of very-high-frequency amplitude modulation to measure the response of optical detectors. This technique does not require a laser with a flat, or even known, frequency response, and measures the detector response at frequencies well above the modulation frequency applied to the

laser. The response of several InGaAs p-i-n detectors was measured to 22 GHz using 1.3- $\mu$ m and 1.55- $\mu$ m semiconductor lasers modulated at 500 MHz. These measurements were not limited by the measurement method, which may be capable of measuring bandwidths substantially in excess of 20 GHz. 19 refs.

**078198 INTERFACE ROUGHNESS/ISLAND EFFECTS ON INTERSUBBAND TRANSITIONS IN QUANTUM WELLS.** We introduce a perturbation approach to study interface roughness/island electron diffraction effects in quantum wells and apply this approach to photoexcitation and infrared detection. Interfacial imperfections spoil the usual selection rules associated with intersubband optical transitions, thereby making transitions due to photons polarized in the plane of the quantum well non-forbidden. This can have a beneficial effect since normal incidence photoexcitation would provide the simplest approach to detector, modulator, and focal plane array applications. A general result for quantum well interfaces with arbitrary (random or regular) island patterns is obtained. Some estimates of the effect are included. In addition, the effect of interface roughness on intrasubband transitions is briefly discussed. (Author abstract) 16 refs.

**078199 GENERATION-RECOMBINATION PROCESSES AND AUGER SUPPRESSION IN SMALL-BANDGAP DETECTORS.** While some noise mechanisms in low band-gap photodetectors are in principle avoidable through the use of optimized growth and device technology procedures, the dominant process in devices working at near ambient temperatures is an Auger mechanism which is a property of the band structure itself. This paper reviews some of the ways in which noise from this source can be largely eliminated. To capitalize on these innovations it seems likely that heterostructure technology will be required in order to avoid extraneous contact related noise problems. (Author abstract) 21 refs.

**078201 DYNAMIC RANGE ENHANCEMENT OF PHOTODIODE ARRAY SPECTRA.** The dynamic range of the photodiode array is typically 30 db. In situations requiring a dynamic range greater than 30 db, the photomultiplier tube is a popular alternative, but the advantage of multiwavelength simultaneous data acquisition - possible with a photodiode array - is lost. A method has been developed to enhance the dynamic range of spectra taken with the use of a photodiode array. A set of spectra is collected under computer control at varied

integration times, and the optimum integration time is chosen individually for each detecting element. (Edited author abstract) 3 refs.

**078204 BIFACIAL, LARGE-AREA SILICON SENSORS FOR RADIATIVE ENERGY SIGNALS.** A comprehensive design/technological study was conducted with the aim of obtaining high-quality, bifacial optical sensors with reproducible parameters on large-area n- and p-silicon wafers. Practical ways of attenuating the severe limitations imposed by different kinds of material (areal) inhomogeneities on the electro-optical performance of large-area single-crystal silicon sensors for radiative energy signals are described theoretically and tested experimentally. Various procedures leading to a substantial increase of both the emitter and the base contributions to the generated photocurrent are implemented and discussed in detail. The test devices were processed on 2 and 3 inch commercially-available silicon and it was sought to minimize the cost of the cells. The combination of simple design/technological approaches described in this work has ultimately led to the development of low-cost, high quality large-area silicon sensors with good overall electro-optical performance as bifacial devices. (Edited author abstract) 18 Refs.

**078205 ULTRAFast INTERDIGITAL PHOTODETECTORS AND INTEGRATION WITH OPTICAL WAVEGUIDES ON SILICON.** The development of new types of high-speed photodetectors and techniques to incorporate these detectors into integrated optical structures are reported in this paper. Schottky-barrier detectors with an interdigital electrode configuration have been fabricated on commercially available silicon-on-sapphire substrates. Response times of < 30 ps have been measured for wavelengths from infrared to the ultraviolet. These experimental results agree well with a supporting numerical model of these detectors. Using the same electrode configuration, we have fabricated photoconductive detectors on bulk silicon and germanium-on-gallium arsenide substrates. These have slower response times, on the order

of a nanosecond, but demonstrate a good responsivity of approximately 1.5 A·W<sup>-1</sup>. Using a modified electrode configuration, we have fabricated an integrated detector array on silicon, combining a glass waveguide channel with each detector element for the efficient delivery of an optical input signal. (Author abstract) 8 refs.

## Electronics Packaging

**078206 NEW STRIDES FOR PHOTODETECTORS.** A growing variety of product lines including local area networks, document and bar-code readers, robots, missiles, medical instruments, and long-haul telephone systems need photodiodes to change light input signals to their analog electrical equivalents. Some of these applications need the detector to be flooded with light; others require the light to be swept across the face of the detector in a beam. Both of these application types now benefit by the trend toward the use of shadow masks etched in opaque material on the diode's surface. The authors discuss opaque coatings, self-encoding masks, packaging trends and performance enhancement.

**Fabrication** See Also SEMICONDUCTOR DIODES, PHOTODIODE—Fabrication.

**078207 RADIATION TOLERANT PHOTODETECTOR.** The development and test of a radiation-tolerant photodetector are described. This was accomplished by building a single-stage photomultiplier tube with a physically small, dielectrically isolated, silicon photodiode array at the anode. In this device the optically generated photocurrent is multiplied by a much larger factor than is the photo-Compton current. Using matched 'signed' and 'optically blind' diodes to differentiate the optical signal from the 'common-mode' ionizing radiation photocurrent also contributes to radiation tolerance. 10 refs.

**Mathematical Models** See SEMICONDUCTOR DIODES, PHOTODIODE.

**Measurements** See Also ELECTRIC MEASUREMENTS—Current.

**078208 MEASUREMENT OF THE PHASE CHARACTERISTICS OF PHOTODETECTORS.** Measurements of the PFC as well as the phase shifts of photodetectors are reported as a function of their spatial shift. The measurements are based on using bimodal lasers with tunable intermodal splitting. The signal from the photodetector that records the radiation intensity of such lasers is, as is known, amplitude-modulated with a 100% degree of modulation (for equality of the intensities and agreement of the mode polarization directions), and frequency modulation is determined by the magnitude of the intermodal splitting. The investigations were performed with photodetectors at the wavelengths  $\lambda$  of visible and infrared spectrum bands lasers. It is shown that the recording part of the installation can be simplified by replacement of the complex phase difference meter by a phase null indicator. In this version the radiation of a bimodal laser proceeding to one of the photodetectors should pass through the calibrated phase shifter. 9 refs.

## Multiplexing

**078209 MONOLITHIC GaInAs/InP PHOTODETECTOR ARRAYS FOR HIGH-DENSITY WAVELENGTH DIVISION MULTIPLEXING (HDWDM) APPLICATIONS.** Monolithic arrays of interdigitated GaInAs/InP photodetectors have been fabricated for high density wavelength division multiplexing (HDWDM) applications. The detectors typically exhibit a reverse leakage current of 400 nA, capacitance of less than 70 fF and a responsivity of 0.5 A/W at  $-5$  V bias. An optical crosstalk of  $-33.4$  dB has been measured between adjacent detectors in an experimental grating demultiplexer system. Preliminary electrical crosstalk measurements in the frequency range of 1-500 MHz indicate signal isolation of the order of 46 dB. (Author abstract). 6 Refs.

Lee, W.S. (STC Technology Ltd, Essex, Engl); Bland, S.W.; Robertson, A.J. *Electron Lett* v 24 n 18 Sep 1 1988 p 1143-1145.

## Noise, Spurious Signal See Also ASTRONOMY—Imaging Techniques.

**078210 NOISE IN THE OPTICAL DETECTION OF ATOMS IN A BEAM.** The noise processes which affect the optical detection of atoms in a beam are identified. A noise factor of the atom to fluorescence photon conversion is defined in the case where the counting statistics of the fluorescence photons can be assumed Poissonian. The signal to noise ratio of the atom detection is given in the case where a photomultiplier or a silicon photocell is used. It is shown that the noise added to the actual atomic beam shot noise can be represented in terms of the shot noise of an equivalent fictitious flux of incident atoms. Results given are applied to the optical detection of cesium atoms. (Author abstract). 16 Refs.

Giordano, V. (CNRS, Orsay, Fr); Candelier, V.; Hamel, A.; Audoin, C.; Theobald, G.; Cerez, P. *Opt Commun* v 67 n 4 Jul 15 1988 p 287-292.

**078211 SHOT NOISE IN PHOTODETECTORS AND VACUUM FLUCTUATIONS.** The photodetection process can be described using the well known approach worked out by Glauber. Recently, Yurke has proposed a different formalism which is especially well suited to the description of the balanced homodyne detection scheme used for the actual observation of the squeezing effect. These two approaches present formulae for the shot noise that are significantly different. In the present paper, it is shown that, nevertheless, these formulae yield results that practically agree, as long as the field commutator involved in Yurke's formula is properly evaluated. (Author abstract). 12 Refs.

Paul, H. (Akad der Wissenschaften der DDR, Berlin, East Ger). *Opt Acta* v 35 n 7 Jul 1988 p 1225-1235.

## Performance See Also OPTOELECTRONIC DEVICES.

**078212 IMPROVED WIDE DYNAMIC RANGE SILICON PHOTODETECTOR FOR INTEGRATION IN IMAGE SENSOR ARRAYS.** A novel silicon photodetector offering several important performance advantages over current industry-standard devices is described. Currently available imaging devices offered by various manufacturers are typically sensitive to varying light intensity over three orders of magnitude in optical power, while this new design offers a logarithmic response of greater than six orders of magnitude in light intensity. Designed to use to advantage the subthreshold effect of short-channel metal oxide semiconductor field effect transistors, the new device is readily integrated into large arrays featuring charge-coupled-device readout shift registers and metal oxide semiconductor support circuitry. Several devices incorporating the new detector have been fabricated and tested, including discrete detectors, linear arrays, and area arrays. (Edited author abstract) 27 Refs.

**078213 CHARACTERISTIC ANGLE AND LIGHT INTENSITY IN DESCRIBING THE POLARIZED STATE.** In a photoelastic-plate-model where membrane  $\sigma^N$  as well as bending stresses  $\sigma^M$  are present, the following quantities are related: the light intensity measured in crossed arrangement of the polarizing filters, the characteristic angle  $\Psi$ , the characteristic phase retardation  $\Delta$ , the angle between the axes of the bending and membrane stresses  $\theta$ , and the ratio between these stresses  $P$ . Based on experimental work, a nomograph that links all these parameters was developed. Entering this diagram with any two parameters shall yield the others. Furthermore, the so-obtained light intensity is introduced as a parameter that contributes to the description of the state of polarization of three-dimensional photoelastic media. In this paper important observations on the experimentally obtained data are presented. (Edited author abstract) 16 Refs.

Issa, S.S. (Univ of Kuwait, Safat, Kuwait); Laermann, K.-H. *Exp Mech* v 27 n 3 Sep 1987 p 298-303.

**078214 SUMMATION STRAIN-GAGE ALTERNATIVE TO OBLIQUE INCIDENCE IN PHOTOELASTIC COATINGS.** A special strain gage (PhotoStress) designed to measure the sum ( $\epsilon_1 + \epsilon_2$ ) of the principal strains, is used in conjunction with photoelastic-coating measurements ( $\epsilon_1 - \epsilon_2$ ) to establish the value of each principal strain ( $\epsilon_1$  and  $\epsilon_2$ ). The summation strain gage is effectively independent of angular orientation (measurement direction), and by design, the gage negates soldering risks, self-heating, and localized-reinforcement considerations normally associated with strain-gage measurements on plastic parts. (Author abstract) 7 Refs.

**078215 BASIC THEORY AND EXPERIMENTAL TECHNIQUES OF THE STRAIN-GRADIENT METHOD.** The theories of presently used experimental methods of stress and deformation analysis which employ radiant energy as a detector are based on the assumption that light propagates rectilinearly within both undeformed and deformed bodies which are initially homogeneous and isotropic when diffraction phenomena are negligible. This assumption is not correct. On the basis of empirical data produced by the authors in the period 1948-1983, this paper presents theories and foundations of the techniques of a new experimental method which is based on the relations between stress/strain gradients and curvatures of light beams. This method is called the strain-gradient method or, less rigorously, gradient photoelasticity. (Edited author abstract) 39 Refs.

Pindera, J.T. (Univ of Waterloo, Waterloo, Ont, Can); Hecker, F.W. *Exp Mech* v 27 n 3 Sep 1987 p 314-327.

**078216 DOUBLE-LIGHT-BEAM METHOD IN THREE-DIMENSIONAL SCATTERED-LIGHT PHOTOELASTICITY.** This paper presents a new scattered-light photo-elasticity technique which may be called the double-light-beam measurement method. Principal-stress directions and relative retardants related to the principal-stress differences can be measured at any point within an ordinary three-dimensional photoelastic model by this method. This method does not need double loading and the quantities to be measured depend only on the relative light intensity. Moreover, the output signals alternate, providing improved accuracy and stability. It supported by an appropriate program-control and digital processing system, the double-beam method can be used to quickly determine the internal stress distribution in

ordinary three-dimensional photoelastic models. (Author abstract) 9 Refs.

Applications See ELECTRIC MOTORS—Components; STRESSES—Computer Aided Analysis.

Measurements See ALSO COMPOSITE MATERIALS—Synthesis; OPTICAL FIBERS—Strain.

**078217 ILLUMINATION OF LIGHT VECTORS MODULATED IN A 3-D PHOTOELASTIC MEDIA.** The dependence of the illumination of a light vector that is subjected to modulation along its path in a three-dimensional photoelastic medium, on the rotation of the principal directions (RPD) of stresses is investigated. The consistency and characteristics of the interaction of the light intensity and the RPD for three different photoelastic materials are explored. The deviation of the rotation of the optical axes from those of the principal ones, in 3-D birefringent material, is illustrated. (Edited author abstract) 9 Refs.

Issa, S.S. *Acta Mech* v 71 n 1-4 Feb 1988 p 157-166.

## Radiation Effects

**078218 EINIGE ASPEKTE DER ANWENDUNG VON GAMMABESTRAHLUNG IN DER SPANNUNGSMESSTECHNIK.** [Certain Aspects of the use of Gamma Irradiation in Photoelasticity]. The results of experimental studies concerning a relatively new method of fixation of photoelastic fringe patterns with the aid of gamma irradiation in the analysis of three-dimensional stress states are presented. The efficiency of this method in comparison with the conventional freezing method is demonstrated in a contact-stress problem. In German. 19 Refs.

Jecic, Stjepan; Goja, Zeljko. *OIAZ Oesterr Ing Archit Z* v 132 n 7-8 Jul-Aug 1987 p 243-248.

## Research

**078219 SOME REFLECTIONS ON CHARACTERISTIC ANGLE, LIGHT INTENSITY AND THEIR CORRELATION TO WAVELENGTH IN THREE DIMENSIONAL PHOTOELASTIC MEDIA.** Some optical phenomena in three dimensional photoelastic media are analyzed. Suggestions made in a paper by S.S. Issa and I. Marie (1986) relative to the experimental technique of integrated photoelasticity are analyzed and some misleading statements of the latter paper are indicated. (Edited author abstract) 3 Refs.

Aben, H. (Estonian Acad of Sciences, Estonia, USSR). *Strain* v 24 n 2 May 1988 p 71.

## Theory

**078220 EFFECT OF STRESS GRADIENT ON THE MINIMUM LIGHT INTENSITY OF 3-D PHOTOELASTIC MEDIA.** The problems associated with the inverse photoelasticity of three-dimensional thin plates and shells are discussed. A novel algorithm for the determination of three-dimensional photoelastic parameters is presented. The detailed processes of data acquisition, storage, interpolation and implementation are explored, with special emphasis on the normalized minimum light intensity as a new characteristic parameter. (Edited author abstract) 11 Refs.

Issa, Sameh S. *OIAZ Oesterr Ing Archit Z* v 132 n 7-8 Jul-Aug 1987 p 230-233.

**078221 HYBRID TECHNIQUES IN PHOTOVISCOELASTICITY.** Photoviscoelastic methods based on various approaches are frequently used in experimental analysis. However, evaluation of the experimental data

taken from material testing measurements to determine the mechanical and optical properties of the viscoelastic model materials, as well as the large quantity of data from the experiment itself, demands extensive efforts in calculation. Therefore algorithms are derived for computer-orientated on-line evaluation according to the principle of 'hybrid techniques'. They are based on the assumption of linear, viscoelastic response and the supposition of isothermal and quasi-static processes. (Edited author abstract) 12 refs.

Laermann, K.-H. *OIAZ Oesterr Ing Archit Z* v 132 n 7-8 Jul-Aug 1987 p 233-235.

**PHOTOELECTRIC CELLS** See Also ELECTRIC MEASURING INSTRUMENTS—Accessories; SEMICONDUCTING GALLIUM COMPOUNDS—Thin Films; SOLAR CELLS; SOLAR CELLS—Silicon; SOLAR RADIATION—Concentrators; TEXTILES—Spinning.

**078222 OPTIMIZING THE OPERATING CONDITIONS OF A PHOTOELECTRIC HYDROGEN UNIT IN VARYING INTENSITY OF SOLAR RADIATION.** Various programs of agreement are suggested, with appropriate choices of switching times, thanks to which further automation of the process is facilitated; photovoltaic systems (PVS) have been developed with adjustable parameters, and an automation unit for switching. Possibilities of automating the process for PVS of various powers are cited. (Author abstract) 5 refs.

Salamov, O.M.; Bakirov, M.Ya.; Rzaev, P.F. *Appl Sol Energy* v 23 n 3 1987 p 16-20.

**078223 SEMICONDUCTOR SEPTUM PHOTOELECTROCHEMICAL CELL.** CdSe semiconductor septum photoelectrochemical cells have been constructed and their photoelectrochemical characteristics studied using cyclic voltammetry. Photovoltages and photocurrent densities as high as 1.8 V and 7 mA cm<sup>-2</sup> respectively were obtained. The changes in polarity of open-circuit voltage and short-circuit current of the cell upon illumination suggest that a rechargeable photoelectrochemical cell may be developed using dual electrolyte semiconductor contacts. (Author abstract) 27 refs.

**Measurements**

**078225 PHOTOELECTROCHEMICAL CELL WITH SEMICONDUCTOR SEPTUM ELECTRODE.** Photoelectrochemical cells consisting of CdSe or CdS pellets separating two redox couples have been studied. The current-voltage relation, output power efficiency, open-circuit voltage and short-circuit current were measured in a two-electrode system. Photovoltages as high as 1.0-1.3 V were obtained. In all cases studied, the power characteristics were linear with low fill factor and output power efficiency. It was possible to improve the performance of such cells by applying external voltage. (Author abstract) 19 refs.

**078227 EFFECT OF MECHANICAL TREATMENT OF ELECTRODE SURFACES ON THEIR PHOTOELECTROCHEMICAL PROPERTIES.** The authors investigated the photoelectric properties of electrodes based on single-crystal and ceramic strontium titanate depending on mechanical treatment of their surfaces. The electrodes' surfaces were treated with powders of abrasive materials. For all the electrodes investigated, the following effects are observed with mechanical treatment of their surface: appearance of photosensitivity in the visible part of the spectrum, an increase in photosensitivity in the ultraviolet part of the spectrum and displacement of the maximum toward longer wavelengths, and a shift in the potential of the plane zones toward positive values. The indicated effects are connected with states in the forbidden zone of SrTiO<sub>3</sub> arising due to weakening or breaking of (Ti-O) bonds, as well as with changes in the electrodes' effective (working) surface with mechanical treatment of their surfaces. 10 refs.

**Calculations**

**078228 INTERPRETATION OF PHOTOEMISSION FROM Na (110).** A self-consistent calculation of the electronic structure of the Na (110) surface, using an embedding method to treat the semi-infinite system, gives

a prominent surface resonance peak at 0.75 eV above the Fermi energy. The tail of this resonance extends below E<sub>F</sub> at the surface, and it is suggested that surface photoemission from this tail is responsible for the peak in the photocurrent at E<sub>F</sub> observed experimentally. A photoemission calculation, with non-self-consistent surface potential, reproduces the enhancement of the peak as a direct transition moves through it. (Author abstract) 15 refs.

**Surfaces**

**078229 RELATIONSHIP BETWEEN PHOTOEMISSION AND PROPAGATION VELOCITY OF LOCAL DISCHARGE ON ELECTROLYTIC SURFACES.** The authors present experimental study results on local discharge propagation along an electrolytic surface under the application of impulse voltage. Experiments were performed using a water channel with point-plane electrodes. The resistivity of the electrolyte (aqueous solution of potassium chloride) was varied from 350 to 3500 Ω-cm. Local discharges propagate on the electrolytic surface and emit light that is more intense at the tip of the local discharge. The discharge velocity and the intensity of the photoemission from the tip of the local discharge were measured simultaneously. It was found that the velocity of the local discharge is determined by the intensity of the photoemission and is independent of the length of the water channel and the applied voltage when the resistance-per-unit-length of water channel is the same. The local discharge propagation mechanism is also discussed. 15 refs.

**078230 ON THE THEORY OF PHOTOEMISSION FROM ADSORBATE-INDUCED SURFACE STATES.** On the basis of a tight-binding model, the photoemission from adsorbate-covered transition metal surfaces is investigated. The photoemission current from the bulk states and the adsorbate-induced surface states is deduced from both poles of the excitation function. The conditions for the existence of surface states for a given overlayer structure are given and compared with the case of a 1×1 structure. The connection between the peak widths and the various lifetimes is elucidated. (Author abstract) 19 refs.

**078232 NOTE ON PHOTOGRAMMETRIC BLOCK ADJUSTMENT WITH ADDITIONAL PARAMETERS.** Photogrammetric block adjustment with additional parameters has found wide application in practice. The additional parameters are used to compensate for possible systematic image errors. In order to come to a clear understanding of the requirements for a unique determination of the additional parameters, we consider a block with minor control points situated at the ideal grid locations on the images. It is shown that one needs as a minimum one additional piece of control information for every additional parameter. In order to ensure a well determined solution, this control should be positioned in one model (image). In summary, block adjustment with additional parameters does not save any work. It equals in work a proper camera calibration done independently before (and after) the photo mission. 1 ref.

**078234 GEOMETRICALLY CONSTRAINED MULTIPHOTO MATCHING.** The Adaptive Least-Squares Correlation, combining gray level matching with geometrical constraints, is applied for X, Y, Z object coordinate determination. The constraints used are the collinearity conditions. A new aspect is the simultaneous use of multiple (more than two) scenes. This paper outlines the mathematical model and highlights some essential features of the algorithm with practical data. Tests using CCD camera data in a close-range environment were performed on the aspects of pull-in range, occlusions, and reliability (multiple solutions, mismatch). In all cases remarkable advantages result from the use of geometrical constraints (conditional one-dimensional search) and multiple scenes. Depth errors of 5% average depth ( $d_0$ ) (6 pixels pull-in range) and 10%  $d_0$  (12 pixels pull-in range) were examined, with 100 percent and 70 percent success rate, respectively. (Edited author abstract) 5 refs.

**078236 ARTIFICIAL INTELLIGENCE IN PHOTOGRAMMETRY.** The scope of the discipline of artificial intelligence is reviewed and its relevance for the discipline of photogrammetry is analyzed. The most appropriate artificial intelligence techniques are dealt with more in detail, especially the usage of heuristics in algorithms, rule-based knowledge representation and programming, and also object-oriented programming. Urgent need for using expert-system technology is seen when replacing semiautomatic man-machine systems with fully automatic systems. In building expert systems, especially in gathering of knowledge as rules, a system-analytical approach is considered to be a necessity. It is concluded that the key issue will be the structuring task in the building of complex systems for photogrammetric analysis - also when gathering the knowledge-base for rule-based programming. (Edited author abstract) 47 refs.

**078240 FROM MAPPING TO MEASURING WITH THE ANALYTICAL STEREOPLOTTER.** The analytical stereoplotter is a modern mapping tool, usually acquired by photogrammetric organizations with a history of providing clients with topographic maps. However, the analytical stereoplotter is much more than a mapping device. It is an extremely versatile and powerful system for extracting measurements from images. The exploitation of system measuring capabilities by a traditional mapping organization is hampered by biases and mind-sets of personnel with only a mapping background. This presents barriers that must first be recognized and appreciated if they are to be overcome. Several of these barriers that have been identified while integrating a modern analytical plotter into a mapping group are discussed. The changing needs of the clients and the obstacles to meeting those needs are also described. (Author abstract) 2 refs.

**078241 APPLICATIONS ARCHITECTURALES DES METHODES NUMERIQUES ET DES EQUIPEMENTS PHOTOGRAMMETRIQUES MODERNES.** [Architectural Applications of Numerical Methods and Modern Photogrammetric Equipment]. In this investigation, by examining successively the six main operations which must or can be undertaken in architectural photogrammetric surveys (operational planning and photography, photographic triangulation, graphic plotting, digital plotting, photographic plotting, file-building and up-dating of surveyed data) and by considering the four main types of photogrammetric systems (analogue, semi-analogue, hybrid, analytic), system-performances with respect to cost, accuracy and quality are compared and practical examples are given. This analysis shows that digital photogrammetry and computer-assisted plotting systems increase the possibilities of using photogrammetry for architectural surveys. **078243 INDUSTRIAL PHOTOGRAMMETRY-ITS APPLICATION TO SHIPBUILDING.** Photogrammetry is the science of acquiring and interpreting three-dimensional data of physical objects by measuring and analyzing their images on photographic plates. The development of this technology since the mid-seventies has increased its credibility for application to industrial and shipbuilding use. Analytical photogrammetry is now routinely employed in shipbuilding for tasks as diverse as predicting the fit-up of structural steel assemblies prior to their joining, verifying the circularity of submarine hulls, and checking the alignment of catapult trough components on aircraft carriers. The authors address the practical applications of photogrammetric technology, and identify the reliability, versatility, and productivity of photogrammetric surveying when applied to shipbuilding. Automation

**078244 AUTOMATION IN PHOTOGRAMMETRIC BLOCK ADJUSTMENT SYSTEMS—ON THE ROLE OF HEURISTIC INFORMATION AND METHODS.** Automation in photogrammetric block adjustment systems is studied, especially the role of heuristic information and methods in automatic systems. The purpose of a block adjustment is considered in the context of the whole mapping process and of the other systems involved in that process. It is shown that heuristic information related to a block adjustment appears in connection with incomplete integration of system components. Heuristic methods are related to the models and strategies used in the block adjustment. State-space representation is used in the detection of gross errors, to emphasize the distinction between goal definition (problem formulation) and the solution techniques. Heuristic techniques are necessary to overcome the computational complexity of the problem. The close relation between heuristic search techniques and weight reduction methods is clarified. The studies on the distribution of test values used in the detection of gross errors reveal that in practice heuristic approximations must be used. (Edited author abstract). 107 Refs.

**078246 USE OF CAMERA ORIENTATION DATA IN PHOTOGRAMMETRY - A REVIEW.** Classical photogrammetric working methods had to solve the problem of camera orientation indirectly by means of ground control points. The performance of new navigation systems will allow in-flight measurement of carrier position and attitude to an accuracy which will change the photogrammetric methods fundamentally. The precision requirements for orientation data on various levels of application (pinpoint photography, combined block-adjustment, direct orientation of photographs and sensors) and the economic advantages are reviewed. (Author abstract) 10 refs.

Ackermann, Friedrich (Inst for Photogrammetry, Stuttgart, West Ger). *Photogrammetria v 42 n 1-2* Nov 1987 p 19-33.

**078247 MULTIPLE EXPOSURES IN NON-METRIC CAMERA APPLICATIONS.** Systematic errors introduced through film deformation constitute a major factor limiting the photogrammetric accuracy of non-metric images. This paper examines the effectiveness of multiple exposure photography in reducing that component of the object-point positioning bias which is due to film unflatness. Aspects of network precision and accuracy are discussed, as are details concerning the additional parameter model selection and the use of orientation constraints. A non-metric camera experiment, in which

multiple exposures were employed, is outlined and the results of this practical application are presented. (Author abstract) 6 refs.

**078249 COASTLINE MONITORING BY REMOTE SENSING.** In order that the structures can serve their protective function over a long (calculable) time and for an extended (calculable) section of the coast, the hydro- and sediment-dynamic processes in coastal waters (on the shore platform) must be exactly known, same as their interaction with structures. All traditional, watercraft-bound methods and explorations are restricted to 'pointwise' working with considerable time gaps in between. A balance sheet obtained in that way shows the various regions in different phases of the process, and soil analyses never cover the entire area. 9 Refs.

**Computer Applications** See Also SURVEYING INSTRUMENTS—Electronics; URBAN PLANNING—Remote Sensing.

**078250 TRANSFERENCE OF METHODS FROM ANALYTICAL TO DIGITAL PHOTOGRAMMETRY.** Photogrammetry has passed through the phases of plane-table, analogue and analytical photogrammetry and we are now facing the next step, digital photogrammetry. In a transition period between phases, old concepts are transferred more or less unchanged to new technology. Examples of transition are given for concepts like DEM measurements in model space, epipolar geometry, adjustment by elements to estimate unknowns, error propagation, and datumsnoping. These concepts are used in multi-point-matching and multi-image-matching in order to increase performance and reliability. Photogrammetrists and computer experts have to co-operate so as to develop and improve digital photogrammetry. (Author abstract) 25 refs.

Torlegard, Kennert (Royal Inst of Technology, Stockholm, Swed). *Photogrammetria v 42 n 3-6* May 1988 p 197-208.

**078251 MICROCOMPUTERS AND PHOTOGRAMMETRY A NEW TOOL: THE VIDEO PLOTTER.** This paper describes the prototype of a plotter. It shows how stereo-images are stored in a digital form and displayed on a screen on which three-dimensional measurements and plotting can be achieved, using a stereoscope, digital mapping techniques, and a measuring mark that has the advantage of being part of the image matrix. An example of interior orientation and plotting is given, using the simple case of a model taken by stereometric cameras. On-going developments, directed at universal plotting, are also presented, along with the main advantages of the new and inexpensive technique. (Edited author abstract).

Data Reduction

**078252 PROJECTIVE ANALYSIS IN PHOTOGRAMMETRY.** As photograph can be considered as central projection, photogrammetry is naturally a topic of

projective geometry. Basing on projective geometry, the author of this paper offers a general analysis of photogrammetric geometry theory and puts forward the photogrammetric equations expressed by homogeneous projective coordinates. In stereophotogrammetry, without knowing the exterior and interior orientation parameters, we can obtain the necessary information (the shape, size and position of an object) by merely measuring and calculating the information of the photograph. (Author abstract) 6 refs. In Chinese.

## Theory

**078260 BASES OF NULL-SPACE IN ANALYTICAL PHOTOGRAMMETRY.** In analytical photogrammetry the concept of null-space is associated normally with 3-D coordinates of object points or of bundle projection-centers. Bases of null-space for all the parameters in a rank-deficient photogrammetric problem become indispensable whenever small variations in datum (S-transformations) have to be implemented. This paper discusses bases of null-space which relate to the orientation angles of a photogrammetric bundle. A simple geometric approach is used for deriving bases of null-space for various sets of orientation angles. The mathematical expressions for evaluating bases of null-space by the proposed method are tested analytically as well as by numerical differentiation. Singular cases are studied and interpreted. **078261 COMPARISON OF SUBMARINE RELIEF FEATURES ON A RADAR SATELLITE IMAGE AND ON A SKYLAB SATELLITE PHOTOGRAPH.** A Skylab photograph and a Seasat radar image of the North American east coast (Nantucket Shoals) taken at different dates, but at the same tidal phase and under comparable weather conditions, are analyzed. It is shown that the radar imaging as well as the optical imaging is caused by roughness variations of the water surface due to tidal flow over submarine relief. It is investigated whether optical imaging is affected by backscattering by suspended sediment in the water column, by reflection from the sea floor or by variations of the surface roughness associated with wind and tidal flow over underwater bottom topography. We conclude from the analysis of the densities in the blue, green and red layers of the Skylab color film that specularly reflected sunlight at the rough ocean surface is the dominant imaging mechanism. (Edited author abstract) 36 refs.

**078264 ELEMENTARY PROCESSES IN LATENT IMAGE FORMATION INVOLVING POLYVALENT CATIONS.** The lower valency states of polyvalent provide donor centers at which electrons may be transferred to the conduction band or holes trapped from the full band of silver halide crystals. The higher valency states provide acceptor centers at which electrons may be trapped from the conduction band or holes transferred to the full band. The transfer processes result from the decay of excitons or the direct absorption of photons at the centers. In the presence of both donor and acceptor centers, electron-hole pairs may be created by a two-step process in which one exciton or adsorbed photon releases an electron to the conduction band from a donor center and a second exciton or photon, a hole to the full band from an acceptor center. (Edited author abstract) 31 refs.

**078265 NEW ROLES FOR SILVER BASED SENSITIZED MATERIALS IN MODERN IMAGING.** The current technologies incorporated into general photography, motion picture production, and photomechanical

reproduction, are continuing to be merged to an ever increasing degree with the more recent imaging technologies, such as electronic imaging, to bring about a wider variety of uses. Through several examples this article indicates that in the production of the color pictorial image, otherwise known as high quality imaging, silver halide based sensitized materials will continue to very ably meet the many requirements essential to these new imaging orientations. Further, within the imaging technology network related to the color pictorial image, the question of the future developmental roles that can be expected of silver halide materials within these new imaging contexts, are delineated and investigated. **078266 DEMBER PHOTOVOLTAGE DUE TO DIFFUSION OF POSITIVE HOLES IN SILVER BROMIDE MICROCRYSTALS.** A Dember photovoltage whose sign was opposite to that of the photovoltage due to the diffusion of photoelectrons was observed on AgBr emulsion grains only in the presence of strong electron traps (i.e., photolytically formed silver clusters and electron-trapping dyes), and was called the negative Dember signal. Hole-trapping dyes prevented the appearance of the negative signal. It is therefore concluded that the negative signal originates from the diffusion of photoholes in the grains. (Author abstract) 13 refs.

**078267 STUDY OF ADSORPTION OF SOME  $Ag^+$ -COMPLEXING AGENTS TO SILVER BROMIDE GRAINS.** A study has been made on the adsorption to silver bromide grains of typical  $Ag^+$ -complexing agents, tetramethyl thiourea (Compound 1), 3,4-dimethyl-4-thiazoline-2-thione (2), potassium thiocyanate (3), and 3,6-dithia-1,8-octanediol (4), by considering their heat of adsorption, orientation on the grain surface, influence upon electric charge of the grains, and desorption of sensitizing dyes from the grain surface. The results have indicated that Compounds 1 and 2 have stronger adsorptivity to the grains than Compounds 3 and 4. It was found from XPS of these agents that sulfur atoms in Compounds 1 and 2 had larger electron density and were more available for complex formation with  $Ag^+$  than those in Compounds 3 and 4. (Author abstract) 4 refs. In Japanese.

## Research

**078268 MICROWAVE DEPOLARIZATION AND DIELECTRIC ANISOTROPY IN KODAK T-GRAIN EMULSION COATINGS.** The orientation of grains in a Kodak T-Grain emulsion coating results in a material with anisotropic dielectric properties. This anisotropy has been observed experimentally via its effect on the microwave photoconductivity of such coatings; the sensitivity of this technique could be altered by a factor of 10-20 by changing the orientation of a T-Grain coating relative to the applied microwave electric field. The experimental results are readily explainable semiquantitatively in terms of electromagnetic depolarization phenomena. Our results show that depolarization effects can be important in influencing the results of microwave photoeffect measurements on T-Grain coatings. (Edited author abstract) 14 refs.

**Sensitivity** See Also PHOTOGRAPHIC FILMS AND PLATES; PHOTOGRAPHIC FILMS AND PLATES—Processing.

**078269 PRODUCTION OF FOG CENTERS AFTER REDUCTION SENSITIZATION BY THE ADDITION OF BROMIDE OR THIOCYANATE.** An increase in fog has been observed from the addition of the silver halide solvents, NaSCN or NaBr, to a reduction-sensitized 5- $\mu$ m polydispersed tabular AgBr emulsion. No fog was observed from the solvent treatment of the nonsensitized emulsion. The addition of a carbocyanine sensitizing dye before the NaSCN or NaBr addition significantly reduced the fog formation. The addition of 4-hydroxy-6-methyl-1,3,3a,7-tetraazaindene (TAI) to the sensitized emulsion before addition of the solvents decreased the fog from the NaSCN, but increased the fog from the NaBr addition. These observations suggest that the nondevelopable silver centers formed by reduction sensitization become developable fog centers when the silver halide solvents are added. (Author abstract) 17 refs.

**078270 ENERGY LEVELS OF SULFUR SENSITIZER CENTERS.** The sensitivity of sulfur- and sulfur-plus-gold-sensitized octahedral emulsions to light of wavelengths  $> 620$  nm has been studied photographically. These measurements have shown that the addition of dyes with low oxidation potentials enhanced the long-wavelength sensitivity of the sulfur- and sulfur-plus-gold-sensitized emulsions. The long-wavelength sensitivity also increased with increasing exposure temperatures. The activation energy,  $E_a$ , calculated from the temperature dependence was  $E_a = 0.33$  eV for the sulfur-sensitized sample and  $E_a = 0.19$  eV for the sulfur-plus-gold-sensitized sample. These results are consistent with a model where the energy levels of the sulfur and sulfur-plus-gold-sensitizer centers are within the bandgap of the silver halide. (Author abstract) 7 refs.

**078271 EFFECTS OF TETRAAZAINDENE ON REACTION AND AGGREGATION PROCESSES IN SULFUR SENSITIZATION WITH THIOSULFATE.** The effects of 4-hydroxy-6-methyl-1,3,3a,7-tetraazaindene as a controller for the processes involved in sulfur sensitization with thiosulfate of octahedral AgBr and AgBrI grain emulsions were studied. Compared with reaction kinetics in the absence of TAI, the reaction kinetics of silver sulfide formation with thiosulfate in the presence of TAI becomes more dependent on interstitial silver ion concentration, or active surface physical defect concentration, and shows resemblances to the reaction kinetics of cubic grains in the absence of TAI. The amount of sulfide required to attain a given photographic speed increases with the presence of TAI, presumably owing to inhibition of sulfide aggregation. As a result, however, TAI has an effect on the size distribution and topography of silver sulfide sensitivity specks, and, under certain conditions, improves sensitometric properties such as high-intensity reciprocity characteristics. (Author abstract) 30 refs.

Takiguchi, Hideki (Konica Corp, Hino, Jpn). *J Imaging Sci* v 32 n 1 Jan-Feb 1988 p 20-27.

**078272 SULFUR-PLUS-GOLD SENSITIZATION: LATENSIFICATION DURING EXPOSURE.** The function of gold in a sulfur-plus-gold-sensitized octahedral emulsion has been studied in bathing experiments, in which the coated film was bathed either before or after exposure. A bath containing a dilute solution of potassium cyanide removes gold, in either ionic or metallic form, from sensitizer centers before exposure or from latent-image centers after exposure. In contrast, gold can be added by the use of a gold-latensifying bath. For high-intensity exposure, gold in the sensitizer centers induces varying amounts of speed through its influence upon the electronic-ionic steps in latent-image formation.

This amount varies both with sensitization and the developer used. For an optimally sensitized emulsion developed in the James surface developer MAA-1, the gold latensification during exposure at  $10^{-4}$  sec contributes about 1 log exposure unit to the photographic speed. (Edited author abstract) 18 refs.

Spencer, Harry E. (Oberlin Coll, Oberlin, OH, USA). *J Imaging Sci* v 32 n 1 Jan-Feb 1988 p 28-34.

**078273 SOME FACTORS AFFECTING QUANTUM SENSITIVITIES OF A SILVER HALIDE EMULSION.** On the basis of data recently published by Hailstone, Liebert, Levy, and Hamilton, it is argued that in a sulfur-plus-gold-sensitized AgBr emulsion exposure generates  $Ag_2$  and larger centers on nearly all grains which have absorbed at least two photons. As contrasted to this efficient creation of centers, the detection of the centers by customary development is not as efficient. The  $Ag_2$  centers are too small to trigger development, unless the grains are light-latensified, which can also increase unwanted fog. Vigorous development needed to detect somewhat larger centers, perhaps three-atom ones, also induces fog, and less vigorous development leads to less fog but only responds to even larger latent-image centers. It is suggested that increased quantum sensitivities can be attained either by more efficient growth of small centers into larger ones or more efficient detection of small centers. Renewed attention to processing details, including suppression of fog, is one way to attack the problem. (Author abstract) 12 refs.

Spencer, Harry E. (Oberlin Coll, Oberlin, OH, USA). *J Imaging Sci* v 32 n 1 Jan-Feb 1988 p 40-42.

**078274 XPS STUDY OF CYANINE DYE ADSORPTION ON AgBr EMULSIONS.** Adsorption of 3,3'-dimethyl-9-ethylthiacarbocyanine iodide on AgBr emulsions was studied comparing previous results on AgCl fused crystal plates. Optical absorption spectra suggested that dye molecules adsorbed on AgBr microcrystals as J-aggregate. Since XPS signal intensities varied depending on gelatin contents of specimen emulsions, intensity normalization based on the substrate bromide signal was utilized. XPS intensity analysis showed that the adsorption of the dye was limited to be monolayer, and iodide, the counter ion in the aggregate, was always detected in the spectra of adsorbed dye layers. The existence of competitive adsorbate, gelatin or fragments, on the AgBr microcrystal surface might lead the dye to J-aggregate formation on adsorption. The surface element of octahedral AgBr was bromide rather than Ag. (Author abstract) 9 refs.

**078275 ENHANCEMENT OF DISPERSION OF LATENT IMAGES BY A CYANINE DYE AS A NEW MECHANISM FOR ITS DESENSITIZATION IN SULFUR-SENSITIZED AgBr EMULSION.** The enhancement of dispersion of latent images by a cyanine dye is proposed as a new mechanism for the desensitization by the dye in a sulfur-sensitized cubic AgBr emulsion. It was confirmed that the dye caused neither densensitization due to its retardation of the development process nor that due to its capture of positive holes by the dye, which was observed in a chemically unsensitized emulsion, was not predominant in a sulfur-sensitized emulsion. The degree of the desensitization observed increased with the increase in the amount of thiosulfate used for sulfur sensitization. (Edited author abstract) 24 refs.

**078276 MINIMIZING PHOTOGRAPHIC SENSITIVITY TO ENVIRONMENTAL RADIATION BY CONTROLLING SILVER HALIDE EMULSION MORPHOLOGY.** AS photographic film speeds are increased by advances in technology, natural background radiation contributes significantly to the degradation of

film performance with age. The goals of this study were twofold: (1) to establish and validate a laboratory model to investigate environmental radiation sensitivity, and (2) to determine a practical way to minimize this sensitivity without photographic performance loss. A natural-aging study of simple model emulsion coatings confirmed that the integrated exposure of film to background sources, which are heterogeneous and polychromatic, can be simulated by 60-cobalt  $\gamma$  radiation, which has a two-line photon spectrum. (Edited author abstract) 35 refs.

**078278 STUDIES OF SUPERSENSITIZATION OF SOME BRIDGED DICARBOCYANINES BY TRIAZINO STILBENEDISULFONIC ACIDS.** IR studies have been made on dicarbocyanines and/or triazino stilbenedisulfonic acids adsorbed on the surface of AgBr grains, and the results indicate that the dye and supersensitizer are adsorbed in a way different from that described by O. Riester due to molecular interaction through opposite charges. Light-induced ESR signals of the dyes and/or supersensitizer added to AgBr emulsion (0.7  $\mu$ cubic) have been observed. It is found that the speed of sensitization increases with increasing intensity of ESR signal in the presence of supersensitizer. (Edited author abstract) 6 refs.

**078279 STUDY OF REACTION AND AGGREGATION STEPS IN SULFUR SENSITIZATION AND THE ROLE OF TETRAAZAINDENE.** A model has been developed for the combined reaction and aggregation processes involved in sulfur sensitization. Limiting forms for the population of aggregates of various sizes have been obtained. The results are compared with experimental data on an AgClBr emulsion. It is concluded that centers containing two sulfides make a substantial contribution to photographic speed. An aggregation rate constant at 80°C is determined for the AgClBr emulsion studied, and this has been used to estimate that about 1000 sulfide pairs/ $\mu$ m<sup>2</sup> confer maximum speed gain under the particular exposure and processing conditions used. (Edited author abstract) 26 refs.

**078280 EFFECT OF S-DONOR LIGANDS ON THE SENSITIZATION OF SILVER BROMIDE CRYSTALS WITH IRIIDIUM(III).** Different levels of potassium thiocyanate were used in combination with potassium hexachloroiridate to surface sensitize an octahedral silver bromide emulsion. Surface sensitivity increased by 0.90 log H over the unsensitized emulsion when IR and SCN were added during sensitization compared to 0.45 log H when the iridium salt is used alone. A decrease of down to 2.40 log H was observed when the Ir-SCN complex was formed and then added to the emulsion. An

increase of 1.05 log H was obtained if gold, thiocyanate and iridium were used. Similar results were obtained using tetramethylthiourea and thiodiglycol instead of SCN. The mechanism of iridium sensitization is discussed based on the experimental results. (Author abstract) 31 refs.

Zuleta, Juan A. (Rochester Inst of Technology, Rochester, NY, USA). *J Imaging Sci* v 31 n 6 Nov-Dec 1987 p 250-254.

**078281 LATENT SUBIMAGE IN A AgBr MODEL EMULSION. 2. SULFUR-SENSITIZED VERSIONS.** Post-exposure light latensification of an optimally sulfur-sensitized AgBr emulsion containing 0.475- $\mu$ m octahedra caused a sensitivity increase of  $-1.0$  log E when the emulsion was developed 12 min in Kodak rapid x-ray developer. The degrees of light latensification decreased with increasing development time and decreasing sulfur level. These experimental results are compared with the predictions of the nucleation-and-growth model of latent-image formation. Quantum sensitivity and degree of HIRF data were used to select the key parameters in the model. Although a unique parameter set could not be found, two parameter sets gave light-latensification values in reasonable agreement with the experimental values. (Edited author abstract) 8 refs.

Hallstone, R.K. (Eastman Kodak Co, Rochester, NY, USA); Liebert, N.B.; Levy, M.; Hamilton, J.F. *J Imaging Sci* v 31 n 6 Nov-Dec 1987 p 255-262.

**078282 STUDY OF THE CHARGE SEPARATION PROCESS IN SPECTRA SENSITIZATION THROUGH AN ANALYSIS OF ITS RELATIVE QUANTUM YIELDS.** The knowledge on the efficiencies of the electron and hole injections by an excited dye is of great importance for the understanding of the mechanism of spectral sensitization. However, it seems that there is no systematic knowledge on  $\phi_4^1$  and  $\phi_4^2$ . This work was undertaken to obtain measuring  $\phi_4^1$  and  $\phi_4^2$  for a series of sensitizing dyes on two typical emulsion grains, i.e., cubic and octahedral AgBr grains whose surfaces consists of (100) and (111) faces, respectively. 14 refs.

**078283 MULTIFLASH RESPONSES OF SULFUR SENSITIZED OCTAHEDRAL EMULSION ORIGINATED FROM COMPETITIVE NUCLEATION EFFECT.** The competitive nucleation or latent image dispersion effect in sulfur sensitized octahedral AgBr emulsion was examined by the multiflash exposure method. As the result of the effect a unique positive multiflash response emerged, where the optical density increased remarkably with the increase of the interruption period  $\Delta t$ , within a definite range of log  $\Delta t$ . A sufficient reduction of the minimum developable size of latent image by gold latensification converted the positive response to a negative type of response commonly observed for chemically unsensitized emulsions. Both the positive and the negative responses, however, were shown to be governed by substantially the same process in silver halides. (Edited author abstract) 12 refs.

**078284 LATENT SUBIMAGE IN A AgBr MODEL EMULSION. 1. SULFUR-PLUS-GOLD-SENSITIZED VERSIONS.** The predictions of the nucleation-and-growth model of latent-image formation regarding the fraction of subimage grains in an exposed emulsion are reviewed. These subimage grains were detected experimentally by using low-intensity light latensification. A AgBr emulsion containing 0.475  $\mu$ m octahedra and sensitized with various levels of sulfur and gold served as a model system. Reciprocity data and the dependence of the D-log E curve shape on exposure intensity indicated that the minimum cluster size which could catalyze development was three atoms for 12 min in Kodak rapid x-ray developer. (Edited author abstract) 12 refs.

**078286 ROLE OF SILVER CENTERS IN THE PROCESS OF CATALYTIC DYE FORMATION.** The goal of this paper was to establish the mechanism of the process of catalytic dye formation. Complex compounds of cobalt(III) were synthesized using familiar techniques. The compounds were identified by elemental analysis for cobalt and carbon, hydrogen, and nitrogen content. The color developer (CD) used was 4-amino-N-ethyl-N- $\beta$ -hydroxyethyl anilinesulfate, purified by activated carbon and recrystallized from an aqueous alcohol solution. Formation of the dye on silver centers was observed for sequential treatment of the photographic paper in a solution of cobalt(III) compounds and then after washing with water in a CD solution. The fact that the dye was not formed when a sequence of treatments was used was evidence for reaction of Co(III) with Ag as the first stage of the process of dye formation. Possible pathway for this reaction are proposed. 24 refs.

**078287 IMAGE IN TERMS OF COVERING POWER.** The design of a system which will result in the formation of a negative transparency in an integral form that is presented in this paper. The stabilization of the internal image depends from the classical means of forming stable, transparent complexes of silver when fixation and wash steps are omitted. In its place a system has been devised which takes advantage of solution physical development to fully develop silver in all areas of exposure including  $D_{min}$ . Image discrimination is effected by differences in the covering power of silver formed at various exposure levels. (Edited author abstract) 4 refs.

**078289 PHOTOGRAPHIC SPEED OF COLOR NEGATIVE FILM BASED ON SIGNAL-TO-NOISE PERFORMANCE.** A new photographic speed criterion for recent ultra-high-speed color negative film 'Graininess-Aimed-Speed' (GAS) is introduced and quantified with a mathematical correlation of signal-to-noise ratio and subjective image evaluation. Since the color negative film exhibits reduced granularity in the direction of

overexposure, the GAS can be specified for the granularity expected on the print. The rationality of the GAS is confirmed in the case of HR 1600 color negative images and their prints produced in various print sizes. We conclude that to add the new speed criterion based on the signal-to-noise performance to the conventional speed criterion is useful for recent ultra-high-speed color negative film. (Author abstract) 7 refs.

**078291 DIRECT PLATE-MAKING SYSTEM WITH THE IMPROVED ULTRA HIGH SPEED PLATES.** HP-system, direct plate-making system which consists of the ultra high speed plate of composite type FNH and the automatic processing system FHP, has been developed in 1980. Recently, in parallel with making great progress in the original making system, users' needs to use the direct plate-making system are notably increasing. Based on above mentioned needs, we have improved the HP system in the following points: 1) Improvement of the image sharpness, resolution and tone-reproduction, 2) Improvement of the spectral sensitivity suitable to Ar ion laser light, 3) Simplification and stabilization of the processing, 4) Development of more compact type processor. Thus, we succeeded in putting in the market: (1) LASER direct plate-making system and (2) Projection direct plate-making system. (Edited author abstract) 11 refs. In Japanese.

**078294 PRODUCING TINTS AND TONES IN MONOCHROME FILMS USING MODERN COLOR TECHNIQUES.** Many early black-and-white films were given artificial coloring by the chemical processing of tinting and toning. Most remaining prints have lost these colors, and the original methods of tinting and toning are rarely practical or economical today. A system of recreating the effect of both tinting and toning has been devised, using modern color-film materials. The technique was applied to the restored copy of the 1927 Australian film classic *For the Term of His Natural Life*. (Author abstract)

**078295 EXPERIMENTAL QUALITY CONTROL PROGRAM FOR PRINTING ARCHIVAL FILMS.** The Preservation Commission of the International Federation of Film Archives (FIAF) has a program for establishing standards for the duplication of archival film. Evaluation of quality in such film is difficult because the preprint is often marred by previous heavy use, shrinkage, and deterioration of the film base. Furthermore, subjective factors influence the overall assessment. The aim of this program is to develop a test film which makes it possible to quantify the various quality factors so that quality assessment may be more objective. (Author abstract)

**078296 FURTHER STUDY OF THE SABATIER EFFECT.** Photographic enlarging papers that show good Sabatier effects with Metol developers are shown to have grains with mainly surface sensitivity centers. We propose a mechanism for the Sabatier effect that is consistent with this observation and with various other phenomena associated with the effect. In this mechanism, grains which received initial exposures corresponding to the minimum in the Sabatier H and D curve have many surface subimage specks and a few internal subimage specks. Metol anions are adsorbed on the surface specks and cause an effective migration of silver to the internal specks, forming internal latent image specks and thus desensitizing the grains toward further exposure to light. (Author abstract) 11 refs.

**078297 EFFECT OF A DISTRIBUTION OF DEVELOPABLE SIZES IN DETERMINATIONS OF THE MINIMUM SIZE OF THE LATENT IMAGE.** Earlier determinations of the minimum developable size were in terms of an abrupt developability criterion and therefore an integral minimum size. We now report an extension of this work to include the concept of a less abrupt transition between developable and undevelopable cluster sizes. When our emulsion is sulfur-plus-gold sensitized, we find that development for 12 min in Kodak rapid x-ray developer at 20°C causes development of all grains whose minimum cluster is three metal atoms and 10% of the grains whose largest cluster is two metal atoms. **078298 THIOUREA AND AMMONIUM THIOSULFATE TREATMENTS FOR THE REMOVAL OF 'SILVERING' FROM AGED NEGATIVE MATERIALS.** Most black and white photographic materials take on a 'silvery' appearance as a consequence of aging. This paper addresses the occurrence of 'silvering' with reference to negative photographic materials and describes the experimental characterization of this phenomenon. It then discusses thiourea and ammonium thiosulfate treatments often recommended for the removal of silvering and demonstrates why these treatments are ill advised. (Author abstract) 15 refs.

## Production

**078300 STABILITY OF LIQUID LAYERS IN COATING PROCESSES: THE STABILITY OF A TWO-LAYER STRATIFIED FLOW ON AN INCLINED PLANE.** The multi-layer slide coating and multi-layer curtain coating methods used in the production of photographic light sensitive materials retain special characteristics in relation to which improvements in coating processes for the slide surface will require the introduction of greater multi-layer flow stability. In this paper, the problem of the fluid flow stability on a flat surface is dealt with in terms of the two-layer stratified fluid flow linear stability theory based on the Orr-Sommerfeld method. ## Stability

**078302 IMAGE STABILITY: NEW MEDIA POSE NEW RISKS.** The steadily increasing dependence on medical diagnostic imaging and the proliferation of imaging systems have focused attention on information quality and permanence. Hardcopy images must be capable of displaying all levels of data initially captured by the diagnostic device and retaining that level of information for as long a period as appropriate for research, medical-legal or government-mandated archival requirements. Image stability has always been a cornerstone of Polaroid instant film design. The company recognizes the silver halide photographic image as one of the densest forms of information storage available; and the retention of key information as an expectation users place on photographic products, instant or otherwise. This article discusses stability tests, competitive imaging media, and thermal systems.

Aberbach, Leonard (Polaroid Film & Research Div). *Ind Photogr* v 36 n 11 Nov 1987 p B26-B28.

## Storage

**078303 PRIME PROVE SULLA CONSERVAZIONE DELL'IMMAGINE REGISTRATA SU PELICOLE RADIOGRAFICHE ARCHIVATE.** [First Tests on the Conservation of the Image Recorded on Archival Radiographic Films]. The aim of this paper is to inform the users about the problem of the stability in time of the radiographic images on films as a function of the film processing and of the environmental storage conditions. The authors stress the importance of optimizing the process and of choosing the most suitable environmental conditions according to different durations of film storage. In fact, no national standards exist so far, which could give exact indications about the tests to be performed for verifying the stability in time of radiographic films. (Author abstract) In Italian. 3 refs.

## Structure

**078304 FNX ULTRA LONG RUN NEGATIVE WORKING PS-PLATE.** Ultra-long run negative working PS plate FNX oriented for a new water based development system has been developed. This plate is made on a multi-grained base on which a newly developed highly light sensitive binder and photo-polymerizable material have been coated. The light sensitive allyl group and alkali soluble group are used in the new binder through which the incorporated light sensitive material is provided with an extra degree of printing durability within the context of a water based development system. This plate is also highly suited to the use of UV ink and in contrast to former plates is also amenable to baking procedures and post-exposure processing for increased impression life. (Author abstract) In Japanese.

**078305 FACTS ABOUT FAX.** In a world where fast communication is often equated with computers, facsimile (FAX) offers speed and simplicity in sending or receiving

communications. FAX can send or receive a page of text or graphics in as little as 11 seconds on a desktop system weighing less than 20 pounds. The article provides brief guidelines for equipment selection.

Anon. *Weld Distrib* v 32 n 1 Jan-Feb 1988 p 65-66.

**078306 USING PIXEL OVERLAP TO OBTAIN MORE GRAY LEVELS IN HALFTONE REPRODUCTIONS.** A new halftoning technique is described that makes use of pixel overlap to attain more gray levels for a given halftone cell size than conventional methods. Although the method has been developed for an ink-jet printing process, it is easily extendible to other processes where the printed spots are larger than the pixel spacing (i.e., thermal transfer, Versatec process, dot-matrix printers, etc.). In such processes, two pixels, for example, may be printed as neighbors so that they overlap, or far apart, so that they do not overlap. A simple model is described for analyzing this method. Selection procedures for determining a base pattern set for an N-level scheme are also discussed, along with some practical considerations. The new method is finally compared with some conventional halftoning techniques. (Edited author abstract)

**Color** See Also IMAGING TECHNIQUES; PHOTOGRAPHIC FILMS AND PLATES, COLOR.

**078308 CREATIVE COLOR COPYING.** Advanced office copier technology has created a new graphics tool. Medical illustrators at Indiana University tested six top machines, and evaluated them on 10 important characteristics indispensable in the biocommunications studio. The machines evaluated were Canon, Minolta, Mita, Sharp, Toshiba and Xerox. Study results are discussed.

Gosling, Craig; Nixon, John. *Ind Photogr* v 36 n 11 Nov 1987 p B37-B39.

**078309 COMPARISON OF HARD COPY TECHNOLOGIES WITH A STRESS ON HIGHLIGHT REPRODUCTION.** To make a hard copy is to realize an image-wise distribution of image forming material on a support. For any hard copy system there must be an elementary quantity of image forming material below which its control is substantially impossible. We measured such elementary quantities in terms of the minimum controllable area covered by image forming material for three systems, i.e., color reversal film, offset printing and inkjet printing. Since the first one is based on intensity modulation, the density fluctuation at highlight was converted into the equivalent fluctuation of area. The result showed that there is almost two orders of magnitude difference between color film and offset print as well as between offset and inkjet prints. It should be noted that the inkjet system treated is 'Jetgraphy' for large format images. Further, a simple model describing noise in offset printing was proposed. (Author abstract) 10 refs. In Japanese.

**078310 ILFORD CIBACOPY SYSTEM 120 PHOTOGRAPHIC COLOR COPIER.** Ilford Photo Corpora-

tion's new Cibacopy System 120 represents an evolutionary advance in automated photographic color copying. The CC-120 is an easy-to-use system designed to produce high quality, low cost color prints and overhead projection transparencies in minimal time directly from positive originals (opaque or transparent) using Cibachrome film or paper in a P-222 process. Options include a device for making copies directly from 35mm slides and an illuminator or light box for making color prints or overhead projection slides from larger format transparencies. The copy system can output up to 120 8½ × 11" prints per hour at an average cost per print of \$.92. Multiple microprocessors and sensors continuously monitor 76 different functions. These and other aspects of the copier are discussed.

Denstman, Hal. *Ind Photogr* v 37 n 5 May 1988 p 47-49.

**078311 PRODUCTION OF COLOUR COMPOSITE IMAGES WITH THE RECTIMAT-C RECTIFIER.** The RECTIMAT-C Precision Rectifier has been available to users for several years. Although it had from the beginning been the design concept of the manufacturer to use the equipment system also for the processing of colour materials, it had not been intended to process multispectral black-and-white film materials for producing color composite images. Practical work with the machine, the high performance of the lenses and the high precision of the moving elements have however shown that under specific boundary conditions the RECTIMAT-C can also be employed for producing colour composite images.

## Computer Simulation

**078312 STUDY ON TONE REPRODUCTION OF POSITIVE WORKING PRESENSITIZED PLATE.** The tone reproduction of positive presensitized plates influenced by exposure and developing processes has been examined by computer simulation. With regard to the dot loss of the plate due to exposure, a very good agreement is obtained between experimental and calculated data by considering both the intensity distribution of incident light and the intensity attenuation of reflected light. The tone reproduction is varied by both the concentration of developers and exposure time. But the effect of the former is less than the latter. Good correlation is found also between dot area and narrow lines. Thus by checking the narrow lines, the tone reproduction on the plates can be administered. (Author abstract) 2 refs. In Japanese.

**Electrostatic** See Also IMAGE PROCESSING—Image Analysis.

**078313 HIGH-QUALITY COLOR PRINTING TECHNOLOGY BY ELECTROPHOTOGRAPHY.** This paper attempts to obtain a high-quality color printing with high speed and high stability. First, the effects of the tone levels and resolution on the image quality were examined. To find their best combination, evaluation experiments were carried out by using various values of the tone levels and resolutions. Second, it was confirmed that electrophotography with an elliptical laser beam scanning is superior to that with a conventional circular laser beam scanning in the tone level and stability. Experiments were done on the former with the conditions which satisfy the forementioned values, by employing the submatrix-type dither. (Edited author abstract) 11 refs.

**078314 CONSTRUCTION AND CHARACTERIZATION OF 12-in. LONG TFEL EDGE EMITTER ERASER BAR FOR ELECTROPHOTOGRAPHIC**

**APPLICATIONS.** A 12-in. long, 20 dpi thin film electroluminescent (TFEL) edge emitter bar was constructed. The purpose was to evaluate if it could be used as an eraser bar in electrophotographic printers. The 12-in. long eraser bar was butted together from four 3-in. long modules. The drive electronics were mounted on a PC board. The electrical interconnects were made using elastomeric connectors. Measurements showed that the output and output uniformity meet the potential user's specifications. Printing tests were made to confirm the high output. Type 7773 dry silver paper was exposed at 1 cm/sec. This paper requires 100 ergs/cm² at 580 nm. (Edited author abstract) 5 refs.

## Equipment

**078315 STEREO PLOT, AN ANALOGUE STEREO PLOTTER.** The current trend in photogrammetry towards universal analytical restitution systems has not impaired the great importance of analogue stereoplotting machines for map production. In the next decade analytical and analogue stereoplotters will continue to be the dominating systems in photogrammetric map production, with analytical machines being preferred for special tasks, while analogue plotters will primarily be used for map production. For such tasks analogue plotting machines will be the most economical solution. Distinguishing features are their simple operation, rugged construction, relatively little maintenance work, high adjustment stability, long life and high accuracy.

Starosczyk, Herbert. *Jena Rev* v 32 n 4 1987 p 180-182.

## Laser Applications

**078316 SILVER TOOLS SENT TO WORK.** The advent of raster plotting has opened up a new era. Shops can now store circuitry in digital form instead of as master plots and then plot artwork in about 4 to 6 min. First-generation phototooling offers a big advantage since a shop can avoid a lot of intermediate steps. Every time a fabricator makes a contact print, there is the potential to introduce scratches, dirt or perhaps most important, a size change. The fewer reproductions to be made, the better. Many shops are already using film off a laser plotter as the final tool. Unfortunately, registration problems have not completely disappeared. Larger panel sizes, tighter boards and more layers are putting increasingly stringent demands on the phototool, both for size holding and for durability. The author examines slotted hole systems, humidity problems and the use of silver-gelatin films.

## Magnetic Field Effects

**078317 MODEL FOR A MONO-COMPONENT DEVELOPMENT PROCESS USING EDGE ENHANCEMENT EFFECTS OF FLOATING ELECTRODES.** The contributions of the electrostatic and magnetic fields to the development characteristics of a monocomponent development system are analyzed. This development system uses a special development roller which comprises a development sleeve and a magnet roller rotating at high speed within the development sleeve. The analysis indicates that the magnetic field has a significant effect only on the toner particles, which are charged below a certain level, but the effect of the magnetic field on the toner particles, which are normally charged above a predetermined level, is negligible. The analysis of the magnetic field indicates that the presently used magnet roller, which rotates at high speed, can be replaced by a micropitch magnet roller, which rotates at low speed. The analysis also indicates that if the quality of the electric charge on the toner particles can be controlled, a nonmagnetic toner can also be used in the present development system. 6 refs.

### Quality Control

**078318 WORKING WITH SUPPLIERS TO IMPROVE PRODUCT QUALITY.** A discussion is presented of four key factors in having suppliers aid in achieving corporate product quality goals. These factors are: the supplier improvement process (SIP); the early production supplier improvement process; certification for parts process; and, supplier performance measure process. The tasks that must be completed prior to involving a supplier are also examined. Two classes of part certification were defined: Class A and Class B. Class A Certification was developed in concert with the B Certification process. Class B is a process based on historical data. Suppliers that manage their processes statistically provide the materials having low parts per million nonconformance, the best delivery performance, the lowest lead times, and the most competitive prices. They will provide the highest value. Class A Certification is our preferred method - the process we are asking our suppliers to use today and into the future.

**Xerography** See Also OPTICAL DEVICES—Electric Properties; ORGANIC COMPOUNDS—Synthesis; PIGMENTS—Physical Properties; SEMICONDUCTING SELENIUM COMPOUNDS—Optical Properties.

**078319 ROLE OF PARTICLES AND DISPERSIONS IN ELECTROPHOTOGRAPHY.** The genesis of the electrophotographic industry can be traced to Chester Carlson who demonstrated in 1938 that dry images could be produced by a process involving the attraction of charged pigmented particles to an electrostatic image formed on a photoconducting film. Carlson's invention, a form of electrophotography, is known as xerography. Most electrophotographic processes are based on the deposition of charged particles in either an air or liquid medium. The marking particles are usually pigments dispersed in a polymer matrix. The various electrophotographic processes are dependent on the electrical and mechanical properties of particles and dispersions. (Edited author abstract) 28 refs.

**078322 PHOTOGENERATING PROPERTIES OF UNSYMMETRICAL SQUARAINES AND SQUARINE COMPOSITES.** Novel unsymmetrical and composite squaraines have been synthesized and characterized as IR photogenerators. These pigments on dispersal in a binder and coating on a conductive substrate followed by overcoating with a hole transport layer give moderate to excellent near IR photosensitivity. (Author abstract) 7 refs.

Kazmaier, Peter M. (Xerox Research Cent of Canada, Mississauga, Ont, Can); Burt, Richard; DiPaola-Baranyi, Giuseppe; Hsiao, Cheng-Kuo; Loutfy, Rafik O.; Martin, Trevor I.; Hamer, Gordon K.; Bluhm, Terry L.; Taylor, Michael G. *J Imaging Sci* v 32 n 1 Jan-Feb 1988 p 1-4.

**078323 TIME-OF-FLIGHT TRANSIENT SIGNALS OF TWO-LAYER ELECTROPHOTOGRAPHIC PHOTORECEPTORS.** The xerographic time-of-flight technique (XTOF) is applied to SeTe two-layer photoreceptors. The shape of the signal as a function of time is explained in terms of a dispersive charge transport in the generator layer and charge injection and transport in the base layer without dispersion. The charge injection into the base layer is calculated from the XTOF signal. A model based on trapping and release events in the generator layer is developed to describe the charge transport. The model is applied to calculate the charge injection into the transport layer as a function of time. The experimental data obtained from the shape of the XTOF signal is fitted to the model and the energy levels and the trap concentration are determined. The trap concentration as a function of energy follows an exponential law. (Author abstract) 17 refs.

Pinsler, Heinz (AEG AG Warstein, West Ger). *J Imaging Sci* v 32 n 1 Jan-Feb 1988 p 5-11.

**078324 MTF ANALYSIS OF XEROGRAPHIC DEVELOPMENT AND TRANSFER.** Xerographic marking engines are widely used in copiers and printers. To succeed in the marketplace, they must be capable of producing high quality images of black lines on a white background, white lines on a black background, halftones, solid areas, text, kanji, graphics, etc. Therefore, it would be very useful to be able to describe the response of the marking engine to an arbitrary image. This can be done for the optics with an MTF (Modulation Transfer Function) model, which describes the blurring produced by the lens. Photoreceptor response is described by the PIDC (Photo-Induced Discharge Curve) which models the nonlinear relationship between exposure and photoreceptor potential. In these models, spatial frequency response is used to model 'blur', and solid area response is used to model nonlinear effects. In this presentation, these techniques will be applied to the development and transfer subsystems of two xerographic marking engines. (Edited author abstract) 4 refs.

**078325 CHARGING EFFECTS OF ORGANIC PIGMENTS IN ELECTROPHOTOGRAPHIC TONERS.** The 'electronic printing ink' for electrophotography is called toner and until recently only black copies and prints were available. However, color hard copy is now becoming increasingly attractive and organic pigments can be used to give color to the toner. They do, however, also influence the toner chargeability. The authors have investigated the influence of organic pigments on the electrostatic chargeability of xerographic toners. These charging effects were studied by measuring Q/M-values of test

toners consisting only of toner resin and 5% pigment. By use of this method, a correlation between toner chargeability and the incorporated pigment is apparent. (Edited author abstract) 13 refs.

Macholdt, Hans-Tobias (Hoechst AG, Frankfurt, West Ger); Sieber, Alexander. *Dyes Pigment* v 9 n 2 1988 p 119-127.

**078326 XEROGRAPHIC APPLICATION OF PLASMA-DEPOSITED AMORPHOUS TETRAHEDRAL MATERIALS.** The progress made in establishing the usefulness of a-Si:H as a xerographic photoreceptor will be discussed. The basic xerographic parameters are defined and the results for a-Si:H will be discussed. These basic figures of merit can be established using relatively small planar samples. However, the ultimate test of photoreceptor performance is the demonstration of its ability to make prints within a xerographic machine. To this end, the fabrication of photoreceptor drums is essential, and Section III will deal with the topic of reactor concepts for their production; a discussion of key process variables and results will be given. Section IV deals with the details of print evaluation, which reveals some problems peculiar to a-Si:H. These are a consequence of the unique feature of this material, viz., the ability to move the Fermi level either by doping or electric field. Finally, a discussion of generic applications for which a-Si:H photoreceptors are or could be used will be given. 40 refs.

**078328 STUDY OF TONER FUSING FOR ELECTROPHOTOGRAPHY (1ST REPORT, THE ANALYSIS OF UNSTEADY TEMPERATURE DISTRIBUTION DURING FUSING).** In toner fusing techniques for electrophotographic machinery, the basic analysis of fusing phenomenon has been required. In the first place, it is necessary to understand the unsteady temperature field in the toner during fusing. Actually, the temperature variation is nonlinear with property changes according to melting. However, even the linear analysis of the temperature field has not been carried out because of the difficulty of the phenomenon. As the first approach to the analysis, the one-dimensional unsteady temperature distribution assumed to be the linear temperature field is analyzed using finite element method. Heat flux which is supplied to the toner layer, thermal properties of the toner and paper, toner layer thickness, paper thickness and toner coverage are measured. The results of these measurements are used in the boundary condition and properties of FEM calculation. In this way, the temperature distribution during fusing is obtained. (Author abstract). 6 Refs. In Japanese.

**078329 ELECTRICAL PROPERTIES OF CONDUCTIVE TWO-COMPONENT XEROGRAPHIC DEVELOPER.** Xerographic development with a conductive two-component magnetic brush depends on the electrical properties of a developer mixture consisting of insulative toner particles and conductive carrier beads.

The electric field driving toner deposition onto an image receiver is affected by the carrier bead conductivity, toner concentration, magnetic field strength, developer thickness, and developer agitation due to the relative motion between the developer and image receiver. To elucidate the dependence of the electrical properties on these parameters, the measurements on an electroded cell of developer under conditions simulating magnetic brush development systems are described. The measurements provide insight into the solid area and line development process with conductive xerographic developer. 7 refs.

Hays, Dan A. (Xerox Corp, Webster, NY, USA). *IEEE Trans Ind Appl* v IA-23 n 6 1987 p 970-974.

**078330 SIMULATION OF TONER DEPOSITING PROCESS IN XEROGRAPHIC IMAGE STUDIES.** A novel concept of insulative magnetic brush (IMB) development which exhibits excellent reproduction of solid-area images while maintaining IMB line image reproduction capability is discussed. The process is based on a simulation of the profile of the electric field in the development zone, the behavior of toner in the development gap, and the balance of charges in the developer in a two-component magnetic brush development system. 10 refs.

**078331 XEROGRAPHIC DEVELOPMENT USING SINGLE-COMPONENT NONMAGNETIC TONER.** No magnetic material is necessary for this system. A thin layer of nonmagnetic toner is formed on the surface of a metal roller by means of an elastic plate which is pressed against the roller. The toner particles are charged triboelectrically by friction with the metal plate. The toner layer is attached to the roller by electrostatic force, and is carried around to the photosensitive drum. The latent image is developed with the noncontact development technique. The insulative toner developed for this system has a superior triboelectric characteristic. A model for toner charging is shown. The numerical calculations based on the model agree well with the experimental results. The model suggests that the metal plate controls the toner charge. 6 refs.

**078332 PARTICLES AND PHOTOGRAPHY.** The technical and commercial developments of photography are outlined. The roles of particles in the black and white and color photographic processes are described in terms of the basic technology of photography. The desired properties of particles in photographic systems are also described. Several illustrations of photographic particles and of particles in photographic systems are presented. An example of the properties of photographic systems that depend on particle properties is also presented. (Author abstract) 3 refs.

**078333 ROTATING APERTURE METHOD OF SPECKLE PHOTOGRAPHY FOR DYNAMIC PROBLEMS I: TWO-APERTURE AND FOUR-APERTURE.** In this paper, a new experimental technique - rotating aperture method of speckle photography for dynamic problem is proposed. The displacement field of any moment of a specimen can be obtained, while simple equipment is needed. Using a rotation device, the whole dynamic process can be recorded on a single specklegram, and then information of every moment can be separated from each other easily by whole-field filtering. This method is applicable not only to vibration

problems, but also to non-periodic dynamic problems. Three experiments have been carried out for demonstration. Speckle fringes are clear and reliable. Quantitative analysis of experiments agree well with the results obtained from other methods. (Author abstract) 6 refs. In Chinese.

### Computer Applications

**078335 COMPUTERIZED PHOTO FILING.** An overview is given of hardware and software available for putting your image information 'on line'. This first part of a two-part article should help you choose the most qualified equipment, hardware and software, best suited to your needs. Discussion of hardware cannot be inclusive because the topic is so broad. But a succinct mention of the available equipment should familiarize you with industry buzzwords, while providing benchmarks so you can make intelligent choices when you computerize.

**078338 HIGH RESOLUTION 9.5-IN. DRY SILVER/WET FILM LBR FOR TACTICAL APPLICATION.** RCA has developed a High Resolution Laser

Beam Recorder (HRLBR) image generator for tactical operation. This ruggedized film recorder uses 9.5-in. film and is designed for tactical shelters. It contains an in-line processor for dry silver film operation providing non-chemical, almost immediate output usable imagery. It also has a take-up cassette for wet film off-line processing operation. The first application was for 8000 picture elements/scan, but this can be conveniently increased to handle 20,000 picture elements/scan. The image data input is computer compatible with many extra control and computer interface setup characteristics. (Edited author abstract)

**078339 MEASUREMENT AND VISUALIZATION OF TWO-DIMENSIONAL VELOCITY DISTRIBUTION BY THE LASER SPECKLE PHOTOGRAPHY USING A He-Ne GAS LASER (1ST REPORT, APPLICATION TO THE FREE CONVECTION FIELD AROUND A VERTICAL PLATE IN AIR AND MEASURING ACCURACY).** The speckle photography technique is one of the most novel velocity measurement methods. This study examines the possibility that this technique will become practically applicable. In this study, this technique is applied to the laminar-free convection field around a uniformly heated vertical plate in air. Moreover, a He-Ne gas laser is employed as the light source in order to enhance the validity of this technique. The measuring results agree with a similar solution within  $\pm 10\%$  at the local velocity  $u(y) = 0.057$  approximately 0.185 m/s. It becomes clear that this technique using a He-Ne gas laser can obtain a whole instantaneous two-dimensional velocity distribution with fair accuracy. (Author abstract) 8 refs. In Japanese.

**078344 SILVER SALTS AND STANDING WAVES: THE HISTORY OF INTERFERENCE COLOR PHOTOGRAPHY.** Gabriel Lippmann's interference color photography is totally disused today, but his ideas and technique were to prove essential for holography. Here we describe first the aborted Newtonian attempts at explaining substantial colors through interference effects analogous to those actually at work in Lippmann's plates. Second, we show how the standing-waves concept passed from acoustics to optics. Third, we follow across the 19th century what now appears to be now a sideline in the development of color photography; the discoveries of Seebeck, Herschel and Becquerel. While these are no longer of any practical importance, their little known story is more complex and perhaps more instructive than that of three-color photography. (Edited author abstract) 83 refs.

**078345 COLOR GAMUT OBTAINABLE BY THE COMBINATION OF SUBTRACTIVE COLOR DYES.** The optimum absorption bands  $D_{opt}(\lambda)$  of subtractive color dyes (cyan, magenta, and yellow) have been determined in color transparencies, by use of a nonlinear optimization technique, at four luminous transmittance levels of  $Y_g = 10, 20, 40$ , and  $80$ . The constraint to the maximum density  $D_{max}$  is imposed in the optimization. The results show that the  $D_{opt}(\lambda)$  cannot be uniquely determined but can be determined as a function of two factors  $Y_g$  and  $D_{max}$ . (Author abstract) 9 refs.

**078346 REDUCTION OF TEMPERATURE RISE IN HIGH-SPEED PHOTOGRAPHY.** This report provides information to professional industrial, scientific, and

technical photographers on filtration with glass and infrared-absorbing and reflecting filters. Glass and infrared filtration is a simple and effective method to reduce the radiation heat transfer associated with continuous high-intensity tungsten lamps. The results of a filtration experiment conducted at the NASA Lewis Research Center are explained. The figures provide starting points for quantifying the effectiveness of various filters and associated light intensities. The combination of a spectrally selective reflector (hot or cold mirror) based on multilayer thin-film principles and heat-absorbing or infrared opaque glass results in the maximum reduction in temperature rise with a minimum of incident light loss. **Industrial Applications**

**078349 HIGH-SPEED CHASE.** Whether the investigation as being conducted to improve a process or to determine why it went wrong, high-speed cinematography provides a dynamic look at the action. Process and product design, materials research, and even litigation can often be aided by using this medium, which has capabilities not shared by videotaping of high-speed still photography. Sometimes the best way to catch problems in a machine or process is to film it at its normal running speed and then slow down the moving image for analysis.

**078353 NEW ASPECTS OF THE SOLVENT MODE IN THE PHOTOINDUCED ELECTRON TRANSFER IN POLAR SOLUTION.** Assuming that the vibrational frequency of possibly coordinated solvent molecules around the charged reactant becomes considerably larger than that around the neutral reactant, we have derived formulas for the electron transfer rate as a function of the energy gap which differ greatly among the three kinds of electron transfer reactions; photoinduced charge separation, charge recombination and charge shift reactions. Those theoretical predictions are in good agreement with the experimental data so far available. By performing the Monte Carlo simulation study, it is confirmed that a considerable dielectric saturation of the coordinated solvent exists around the molecular ion and a substantial difference of the potential curvature is realized for the coordinated solvent mode around the charged molecule from that around the neutral molecule. ## Analysis

**078355 EXTRINSIC PHOTOLUMINESCENCE IN COUPLED-WELL SUPERLATTICES.** Extrinsic luminescence involving residual donor and acceptor impurities in a nominally undoped, coupled-well 80 Angstroms GaAs/20 Angstroms  $Al_{0.3}Ga_{0.7}As$  superlattice grown by organometallic chemical vapor deposition has been investigated. Separate peaks are observed in the luminescence lineshape corresponding to acceptors in the barriers and in the wells, with ionization energies of about 13.5 and 31.9 meV, respectively. The relative amplitudes of the peaks indicate that most of the acceptors are located in the AlGaAs barriers. Varying the temperature from 1.7 to 31 K and the excitation intensity from 0.28 to 1400 mW cm<sup>-2</sup> reveals both donor-to-acceptor and miniband-to-acceptor recombination involving each type of acceptor. (Author abstract) 21 refs.

## Theory

**078358 INITIAL PHOTOLUMINESCENCE DECAY RATES IN AMORPHOUS PHOSPHORUS.** Previous measurements of the photoluminescence of amorphous phosphorus have not been able to distinguish between two models of the time-dependent shift of the emission energy of the early radiative recombination. This may arise from recombination of carriers trapped at charged defects or from thermalization of a carrier in a tail of localized states. The present work extends the time resolution of the luminescence measurement to approximately 50 ps which enables a distinction to be made between the two models. The initial decay rates for luminescence in the photon energy ranges 1.45 - 1.6 and 1.45 - 1.85 eV are the same to within approximately 1% at 4 K, which supports the assignment of the recombination to carriers trapped at oppositely charged intrinsic defects. The temperature dependence of the initial decay follows the empirical law  $v(T) = v_1 + v_0 \exp(T/T_0)$  with  $v_1 = 8.6 \times 10^8 \text{ s}^{-1}$ ,  $v_0 = 3.7 \times 10^8 \text{ s}^{-1}$  and  $T_0 = 104 \text{ K}$ . A temperature-dependent branching between two radiative channels is proposed in order to reconcile these observations with earlier work. (Author abstract) 10 refs.

**078359 DIGITAL VIDEO LIGHTMETER TESTS DISPLAYS.** Evaluating the luminance and radiance values of illuminated avionic displays typically involves the use of spot photometers. To test luminance uniformity, three 'spots' are read on each character of the displays. A new technology offers an alternative to spot photometer testing. The Korr digital video lightmeter (DVL) utilizes digital video techniques to produce a color-coded representation of any portion of an illuminated surface - from individual characters to an entire legend. The system consists of four main components: a solid-state CCD camera and lens, a photopic correction filter, a dedicated microcomputer with special image processing circuitry and hardware, and a color monitor.

**078360 REDUKCJA BLEDU METODY POMIARU STRUMIENIA SWIETLNEGO W LUMENOMIERZU, PRZEZ ZMIANE WARUNKOW OBIEGU STRUMIENIA SWIETLNEGO WEWNATrz KULI FOTOMETRYCZNEJ.** [Error Reduction of Measurement Method of Luminous Flux in an Integrating Sphere by Changing Circulation Conditions of Luminous Flux Inside Photometric Sphere]. The technique of covering surface of a photometric sphere with a coating of varying reflectivity coefficient is proposed. This coating diminishes a systematic error of luminous flux measurement caused by the lack of geometric similarity of the light distribution in sources of the measuring set. The reduction of the effective reflectivity due to this coating will also reduce systematic errors connected with dissimilarity of spectral distributions of radiation as well as with share of the arrangement sources in reflection and absorption of the luminous flux. (Edited author abstract) In Polish. 16 refs.

**078361 FILTER PENETRATION MEASUREMENTS USING A CONDENSATION NUCLEI COUNTER AND AN AEROSOL PHOTOMETER.** We conducted both theoretical and experimental comparisons of two instruments, a condensation nuclei counter and an aerosol light-scattering photometer, to determine how they measured the penetration of high-efficiency particulate air (HEPA) filters. In some experiments we simulated leaks around the test filter to ascertain how such leaks affect the two instruments' penetration measurements. Results of all of the experiments indicate that differences in the measurements vary widely from no difference to a factor of 10. These variations are related to certain functions that depend on particle size: the response function of the photometer, the filter penetration, and the distribution of the test aerosol. (Edited author abstract). 18 refs.

## Calibration

**078362 METHOD OF DETERMINING PHOTOMETER CALIBRATION CHARACTERISTICS.** A computational experiment was performed with  $u = \log(1 + 100\tau)$  as the test function, which showed that with  $\tau_0 = 0.5$ , five multiplicative tests provided an approximation with an accuracy better than 0.2% for a dynamic range of two orders. The author shows the approximation for  $u =$

log  $(1 + 100\tau)$ , as a polynomial of degree  $n$  obtained in multiplicative tests:  $n = 3$  (a),  $n = 4$  (b), and  $n = 5$  (c). Here 1 and 2 are different sets of filters with unknown transmissions. The experiment shows that one can provide an error in the calibration curve within 1.0% by calibrating the  $\tau_0$  filter with an accuracy better than 0.05% if the instrumental error is  $\delta\tau_0 \leq 0.01\%$ . This method does not involve any essential difficulties, so it can be widely used in calibrating commercial photometers. 5 refs.

**078363 DEVICES FOR CHECKING PHOTOMETRIC ANALYZERS.** Spectrophotometric analytical instruments are evaluated by a collection of characteristics following GOST 8.009-84, expressed in units of the concentration of the material being determined. Instruments of this type are calibrated and checked using standard samples of the materials or certified solutions whose composition is known. In order to calibrate and check photometric scales, attenuators made of neutral glass of the NS type for the visible region of the spectrum and quartz attenuators with vacuum deposition of metallic coatings for UV, visible, and near-IR regions of the spectrum (190-2500 nm) are most widely used. The main factors determining the use of glass and quartz attenuators are their good spectral and photometric characteristics. 2 refs.

**078365 DEVELOPMENT AND PERFORMANCE OF AN AUTOMATED MOVING ARM GONIOPHOTOMETER FOR MEASURING THE SPATIAL DISTRIBUTION OF LIGHT OF LUMINAIRES.** An automatic photometer for measuring the spatial distribution of light of luminaires has been designed and built in INTI in Buenos Aires, Argentina. An arm 7.5 m long, on the end of which the photoelectric detector is fixed, moves in a vertical plane. A maximum angle of elevation of  $130^\circ$  can be obtained. The luminaire rotates almost a full circle in the horizontal plane. The system is controlled by a desk computer. A brief description of its performance and some construction details are given. (Author abstract) 8 refs.

**Errors**

**078366 UNDERCOMPENSATION ERROR OF TWO-CHANNEL ABSORPTION PHOTOMETERS.** Absorption photometers (AP) are an important part of a large group of analytic instruments for studying the composition and properties of liquid media. Among the AP there is a subgroup of instruments which are used for measuring the optical density of the medium under study and whose output signal is a linear function of the measured parameter. The article presents a theoretical evaluation of the errors of AP schemes with sequential conversion owing to the characteristic noise of the circuits and the instability of their parameters. The operation of the AP is based on the dependence of the magnitude of the

radiation flux passing through the medium under study on the absorption of the medium. 5 refs.

**078368 INTERNATIONAL INTERCOMPARISONS OF PHOTOMETRIC BASE UNITS.** In order to evaluate the worldwide consistency of practical implementations of the 1979 redefinition of the candela, the Consultative Committee for Photometry and Radiometry (CCPR) has conducted an international intercomparison of photometric base units. The intercomparison showed 0.8% agreement (one standard deviation) of independent luminous-intensity scale realizations by 15 national laboratories, and 0.6% agreement of luminous-flux scale realizations by 11 laboratories. The NBS candela and lumen agreed with the world mean within quoted uncertainty limits, and were shown to be consistent with one another within 0.5%. (Author abstract)

**Research**

**078369 ALTERNATIVE SUBDIVISION FOR THE SKY VAULT.** An alternative to Tregenza's recent scanning pattern for sky photometry is presented and discussed. Tregenza has described an ingenious method of packing the surface of a hemisphere with a large number of identical circular caps in such a way as to cover, in parallel bands, without overlap, the largest possible proportion of the hemisphere surface. The resulting array of circular caps defines a pattern of aiming points, and the (constant) acceptance angle, for a photometer programmed to sample the directional luminance of the sky vault. This note reports a packing study for the same application, but the requirement for identical caps is relaxed; caps at different altitudes may have different diameters. 3 refs.

**078370 DETERMINATION OF THE DOSE EQUIVALENT DISTRIBUTION IN THE ICRU SPHERE FOR PHOTON RADIATION.** For practical radiation protection purposes with regard to photon irradiation, different types of dose equivalent quantities within the ICRU sphere phantom are summarized and the corresponding fluence-to-dose equivalent conversion factors stated for photon radiation. The quantities considered are the dose equivalent index, the dose equivalent at specified depth, special mean values, and a geometry factor which might be of interest in multidirectional irradiation fields. Details are given for the calculation determination of dose equivalent distributions within the ICRU sphere using the Monte Carlo method and for the experimental determination of dose equivalent quantities by means of TL-dosimeters and ionization chambers in the photon energy range between 10 keV and 10 MeV. (Edited author abstract) 31 refs.

**078371 SATURATION OF TWO-PHOTON ABSORPTION IN STRAIGHT-BAND SEMICONDUCTORS.** Within the framework of the Klein model, two-photon absorption in straight-band semiconductors of type GaAs is theoretically investigated. The limiting cases of fast ( $\tau_p \gg T_v$ ) and slow ( $\tau_p \ll T_v$ ) intraband relaxation are considered; here  $\tau_p$  is the duration of the light pulse;  $T_v$  is the time of intraband relaxation. It is shown that dynamic variation in the saturation difference is the basic mechanism of saturation of two-photon absorption of a straight-band semiconductor by picosecond pulses, up to the intensities of the order of 600 MW/cm<sup>2</sup>. (Author abstract) 5 refs.

**078374 NEUTRON-INDUCED PHOTON PRODUCTION CROSS SECTIONS.** A procedure for the determination of neutron-induced production cross sections is described, including corrections for the neutron-induced photon background and the unfolding of the gamma-ray spectra. As an example, data have been obtained for tantalum and beryllium with five bismuth germanate detectors and the high-energy white neutron source at the Los Alamos Meson Physics Facility. Calculations and measurements indicate that a beryllium sample may be used to simulate a neutron-induced photon background. Results for the  $Ta(n,\gamma)$  reaction for neutron energies below  $E_n=20$  Mev are compared with previous measurements at the Oak Ridge Electron Linear Accelerator. (Author abstract) 17 refs.

**078375 RADIATIVE PROCESSES IN HIGH-ENERGY ION-ATOM COLLISIONS.** Instantaneous photon emission in ion-atom collisions is considered from the standpoint of theoretical consistency. The processes discussed include electron bremsstrahlung, radiative electron capture, and atomic bremsstrahlung. Particularly detailed discussion is made on radiative electron capture. Formulas based on nonrelativistic quantum mechanics and on semiclassical theory are found to conflict with each other. This inconsistency is removed by taking the gauge-invariance requirement into consideration on the matrix elements of the interaction of the particle system with the radiation field. Finally, we present an approximation method that satisfies the gauge-invariance requirement. In addition, we show the results of calculations for radiative electron capture by  $Xe^{34+30}$  and by  $U^{92+30}$  from Be as examples and compare them with experiments as well as calculations based on existing theories. **078377 LIGHT ABSORPTION BY A COLLISIONAL SYSTEM.** Perturbation theory is applied to the interaction between a binary collisional system and a weak radiation field to obtain the rate of induced absorption or the line profile of an optically allowed transition at low density. The collisional system wave functions are not affected by the radiation field and appropriate different expansions of these functions must be used for the two electron-atom or atom-atom systems under study. Unified expressions of the profile are given which converges to the impact limit at small detunings. The semi-classical approach of the collisional problem is given to underlie the correspondence with the usual autocorrelation formalism. Both approaches break down for large detunings where a quantum collisional theory must be used. (Author abstract) 47 refs.

## Sensors

**078385 ULTIMATE PARAMETERS OF MIDDLE AND LONG WAVELENGTH INFRARED DETECTORS (Cd, Hg)Te BASED ON THE DEMBER EFFECT.** Intense research being conducted in many research centres with a view to making use of various physical phenomena to construct (Cd,Hg)Te detectors of medium and far infrared. However, the theoretical and experimental research is concentrated chiefly on the construction of photoresistors, photodiodes and PEM detectors. As regards the theoretical analysis of such detectors, the influence of Dember effects is usually disregarded. The present authors make an attempt, for both cognitive and practical reasons, to appraise the properties of (Cd,Hg)Te Dember detectors, by comparing the Dember effect with photoelectromagnetic effect. 9 refs.

**078391 POLYMER MATERIALS FOR MICROLITHOGRAPHY - ELECTRON BEAM RESISTS.** Polymers play a critical role in both the fabrication of masks and the patterns required for micro circuit construction. In an earlier article, the chemistry of photo resists was extensively reviewed. Currently, photo resists are capable of being used in the fabrication of circuits with dimensions down to one micron and it is possible that through modification of conventional materials and the use of shorter wavelength sources that this technology will be extended down to sub-micron dimensions. The next generation of very large scale integrated circuits (VLSI) will require the production of patterns with structures having dimensions as small as 0.4 microns. To generate these patterns it is necessary to produce highly perfect masks and this is best achieved by use of electron beam lithography. (Author abstract) 47 refs.

**078393 ORGANOSILICON DEEP UV POSITIVE RESIST CONSISTING OF POLY(P-DISILANYLENEPHENYLENE).** A new class of positive deep ultraviolet (UV) resists consisting of poly(p-disilanylene)phenylene)s was developed, in which a disilanylene unit and a phenylene unit are connected alternatively in the polymer main chain. These resists had very high etching resistance against oxygen plasma. The lithographic applications of a double-layer resist system in which the poly(p-disilanylene)phenylene film was used as the top imaging layer were examined. As a result, very high resolution and high contrast were attained. The double-layer resist technique using organosilicon deep UV positive resist appears very promising for lithographic applications. (Author abstract) 8 refs.

Nate, Kazuo (Hitachi Ltd, Yokohama, Jpn); Inoue, Takashi; Sugiyama, Hisashi; Ishikawa, Mitsuo. *J Appl Polym Sci* v 34 n 7 Nov 20 1987 p 2445-2455.

**078394 TAPERED RESIST WALL PROFILES BY FLOOD EXPOSURE.** A resist wall profile tapering procedure is proposed for positive resist systems that are normally designed to produce near vertical profiles. A flood exposure step has been added, but no change in the softbake, develop, or postbake procedure is required. At the same contact hole dimension, different ratios of flood to pattern exposure dose produce different slopes for the resist profiles. The unexposed resist film thickness loss can be used to monitor the resist tapering results. SAMPLE resist exposure and development simulations are done to analyze the effects of substrate reflectivity, thickness variations, and postexposure bakes on the resist wall profile at various flood exposure dose fractions. (Author abstract) 15 refs.

**078395 SILOXANE POLYMERS AS SENSITIVE ELECTRON RESISTS.** Future generations of integrated circuits will require a higher density of devices on a single chip in order to be commercially viable and consequently individual devices will need to be smaller. The limits of conventional (optical) lithography are such that increasing use of other forms of pattern generation, e.g., electron or X-ray lithography, will be required. The newer forms of lithography require improved resists in order to obtain reliable pattern dimension below 1  $\mu$ m. 2 refs.

Whipps, P.W.; Stearn, G.M. *Annu Rev Philips Res Lab* 1986 p 41-43.

**078396 NEGATIVE, DEEP-UV RESIST FOR 248 NM LITHOGRAPHY.** The negative tone deep ultraviolet resist described in this paper is based on a novolak resin. The chemistry of this negative resist is based on an acid-hardening resin system. A novolak resin combined with an acid activatable cross-linker and a photoacid generator (PAG) comprise the resist. Exposure to high energy photons (below 320 nm) converts some PAG to acidic species. These acids catalyze the formation of several covalent bonds between the novolak and the substituted melamine cross-linker. A postexposure bake accelerates the cross-linking reaction. High contrast is obtained because the appropriate exposure dose and postbake process render the resist nearly insoluble in the developer. Thus, the high ratio of the unexposed to exposed dissolution rates of the resist provides high

contrast, high resolution resist images.

**078397 OPTIMIERUNG DER CHEMISCHEN ZUSAMMENSETZUNG FUER GaAs-PROZESSE: POSITIV-FOTORESIST FUER DEN EINSATZ IM MITTLEREN UV-BEREICH.** [Optimization of the Chemical Combination for GaAs Processes: Positive Photoresists for the Application in the Middle UV Region]. Use of the middle UV spectral region (from 365 to 312 nm) brought about improvements and optimization in the photolithography of chip production, which are possible only with photoresists, the spectral sensitivity of which lies within this region. New positive photoresist combinations have been developed in order to meet these demands. As a result, the photoresists Dynalith X 1608 and X 1605 were developed which are described. 20 refs. In German.

**078398 CALORIMETRIC CHARACTERIZATION OF PHOTSENSITIVE MATERIALS.** A negative-acting dry-film photoresist was examined via both photocalorimetry and conventional calorimetry. The photo reaction of the resist was investigated as a function of temperature, and two distinct regimes with different activation energies have been identified. Possible reaction mechanisms were discussed in terms of termination reactions of the polymerization as well as effects of vitrification. The thermal reactivity of this particular resist was studied as well. It was possible to use Kissinger's equations to predict thermal aging effects. Finally, the utility of photocalorimetry as a tool to examine quickly the reactivity of monomers and initiation systems was demonstrated. (Author abstract) 16 refs.

**078399 FTIR AND UV/VIS STUDY OF THE INTERFACE BETWEEN PMMA AND DYED POLYIMIDE THIN FILMS.** A modified bilayer resist scheme was studied that used a poly(methyl methacrylate) (PMMA) as the bottom, deep ultraviolet (DUV) resist, a novolak-based system as the top near ultraviolet (NUV) resist, and an intervening antireflective coating (ARC). The ARC consisted of a polyimide film formed by the thermal curing of a solution of polyamide acid, dyes, and solvents that was applied to the PMMA layer by spin-coating. An interfacial layer was found to form at the PMMA/ARC interface that remained after the NUV resist and ARC were striped prior to the UV exposure step. Fourier transform infrared (FTIR) and ultraviolet/visible (UV/VIS) spectrophotometries were used to characterize the extent of formation of the interfacial layers as a function of the ARC curing process. (Edited author abstract) 14 Refs.

**078400 RESIST OVERVIEW.** This paper gives a general overview of the important parameters and trends in the evolution of positive optical resists as they still form the workhorse in advanced lithographic applications. We discuss the basic lithographic requirements for the application of resist systems in semiconductor fabrication. From that starting point we show how process control and sophistication on the one hand and materials improvements on the other have made the important increase

in performance of these resist systems possible. Finally the future of positive resists is related to the new challenges of sub-0.7  $\mu\text{m}$  lithography. (Author abstract) 9 refs.

**078401 RESIST IMAGE ENHANCEMENT BY UV-, SOFT VACUUM PULSED ELECTRON BEAMS AND ORGANOMETALLIC COMPOUNDS.** UV-hardening/photostabilization process is used for preventing thermal flow of resist images at high temperatures. Because of high temperature stability and highly cross-linked nature of resist surfaces, UV-hardening is used for resist enhancement for reactive ion etchings of metals, high temperature sputtering, lift-off and others. We present here multilayer resist applications using highly crosslinked resist surfaces. Because of large deep UV absorption coefficients, application of UV-hardening to thick films is limited. For thick resist films, resist stabilization by pulsed electron beams operating in soft vacuum is far more efficient because of deeper penetration of electron beams of 25 KeV energy. The present technique has an advantage over a conventional CW electron source with a larger diameter, cold cathode of an ordinary metal operating in a soft vacuum with high efficiency. Exposures of resist images to organometallic compounds either in vapor phase or in solutions provide them specific RIE resistances and thermal flow resistance. (Author abstract) 13 refs.

**078402 WET AND DRY DEVELOPABLE PHOTOSENSITIVE DEEP UV RESIST.** The PMMA-bisazide resist, containing a deep UV sensitizer (3,3'-diazodiphenyl sulfone) was found to reverse PMMA from positive tone to negative tone, and the sensitivity of this resist was enhanced by a factor of 40 compared to normally used positive tone PMMA. The optimum bisazide concentration was determined to be 25 wt% (based on PMMA weight) to give the highest sensitization and best lithographic results (capable of submicron resolution). This resist was also found to be dry developable by oxygen plasma and the resolution can go down to 1-2  $\mu\text{m}$  lines/spaces although the remaining thickness after development is around 20-30%. 7 refs.

**078403 A- AND B-PARAMETER DEPENDENT SUBMICRON STEPPER PERFORMANCE OF POSITIVE TYPE PHOTORESIST.** A systematical investigation of the g-line stepper performance of positive type photoresists with varying absorption properties has been carried out on highly reflective substrates. Numerous parameters such as photospeed, pattern profile, focus and exposure energy latitude are evaluated by SEM inspection of submicron resist lines after exposure with a stepper of NA=0.42. It is shown that the amount of non-bleachable absorption (B-value) alters only slowly the imaging properties of the resists on aluminum surfaces, whereas changes in the bleachable absorption (expressed by the A-value) lead to large differences in the resist profiles and the tolerance of the lithographic process. Profile simulations with PROSIM and PROLITH indicate that the development characteristics rather than the optical properties determine the performance of the resists. (Author abstract) 12 refs.

## Absorption

**078405 DISPELLING THE MYTHS ABOUT DYED PHOTORESIST.** When light passes through a thin photoresist film coated on a reflecting substrate, a standing wave is produced within the film which can significantly degrade fine line photoresist patterns. Absorption parameters are measured for dyed resists. The effects of absorption on standing waves are determined rigorously and linewidth control is investigated. Finally, the drawbacks of dyed resists are discussed. (Edited author abstract) 28 refs.

## Additives

**078406 CONTRAST ENHANCING ADDITIVES FOR POSITIVE PHOTORESIST.** Adding catalytic amounts of acidic organic compounds, such as phenols and carboxylic acids, to positive photoresists induced the formation of surface skin, leading to increased photoresist wall angles and higher resolution. When the additives were dyes and added at levels which absorbed significantly, at the actinic wavelengths, linewidth variability over topology was reduced without a reduction in the wall angles of the patterned features. For example, dyed resist matched to the g-line stepper gave less than 0.1  $\mu\text{m}$  linewidth variability over reflective tantalum disilicide islands compared to 0.24  $\mu\text{m}$  (1) for undyed resist. The wall angles for both resists were 85°, and the dyed resist required an exposure dose only two times greater. A partial mechanism was suggested for the formation of the surface skin during softbake. (Author abstract) 19 refs.

**Applications** See Also LITHOGRAPHY—Photolithography; SUPERCONDUCTING DEVICES—Josephson Junctions.

**078407 APPLICATION OF HEAVILY DYED PHOTORESIST TO WAFER PRODUCTION.** This article describes the use of heavily dyed photoresist in patterning wafers in production. The dyed resist is made by adding the commercially available 1-(2-pyridylazo)-2-naphthol dye to AZ 1350J-SF photoresist, which is then exposed using g-line steppers and spray-developed with metal-ion-free developer. The resultant images have greater than 80° wall angles and excellent linewidth control over reflective topography. The resist is characterized with respect to linewidth control over large islands, and wafer-to-wafer and across-the-wafer uniformity. (author abstract) 13 refs.

**078408 PHOTOPOLYMERS IN NEWSPAPER PRINTING: A NOVEL APPLICATION OF PHOTORESIST TECHNOLOGY.** By making it feasible to put a large number of identical copies on the market at any given time, Gutenberg set into motion technological advances that make possible the production of an ever

increasing number of copies while reducing the time needed for their issue. Printing is a technical process; as such, it responds to the same technological changes that fuel other industrial advances. The use of radiation curing technology has made possible developments in printing plates that rival the mechanical developments of the printing presses themselves. Photopolymer technology has made newspaper production faster, safer and of the highest quality ever achieved. 3 refs.

Wagner, William R. (Napp Systems (USA) Inc). *Radiat Curing* v 14 n 4 Nov 1987 p 2-7.

**078409 ORGANOSILICON PHOTORESIST FOR USE IN EXCIMER LASER LITHOGRAPHY.** An investigation of an organosilicon resist for use in deep UV excimer laser lithography was performed. The resist is based on the poly(vinylphenol) resin, and was found to exhibit transparency at 248 nm comparable to the transparency of g-line light in conventional novolak resists, making single-layer resist processing possible. The results of single-layer patterning on an excimer laser contact printer are presented. Results are also presented for a bilayer resist process using oxygen RIE etch for transfer of the top layer pattern into a thick underlying novolak layer. (Author abstract) 5 refs.

## Computer Simulation

**078410 SIMULATION OF POST-EXPOSURE BAKE EFFECTS ON PHOTOLITHOGRAPHIC PERFORMANCE OF A RESIST FILM.** Developed relief images in positive photoresist subjected to various levels of post-exposure bake are modelled and simulated using the computer simulation program SPESA. The bake process is represented by simple diffusion of the photoactive compound distribution that forms the latent image before development by a solvent. Quantitative performance criteria such as thickness contrast, sidewall angle, exposure dose requirement, develop time latitude, nodality sensitivity, and exposure latitude are extracted from the simulated resist profiles. When these criteria are examined as functions of the phenomenological diffusion length that parametrizes the post-exposure bake model, we observe a well-defined optimal diffusion length that precedes the threshold for standing wave removal in the relief image, and for which an order tenfold enhancement in develop and exposure latitudes is predicted. The dose requirement also tends to be reduced. Thus post-exposure bake appears to improve the photolithographic process within the context of the simple diffusion model. Refinements relating to the model are discussed. (Edited author abstract) 20 refs.

## Diffusion

**078411 DIFFUSION IN AZ-5214 IMAGE REVERSAL PROCESS AND ITS APPLICATION TO E-BEAM PROXIMITY EFFECT CORRECTION.** Here we report our discovery of the diffusion phenomenon of AZ5214 resist during a post-exposure bake process step and its application to improve the electron beam lithographic performance of the resist. The diffusion phenomena are that the exposed features gain an extra amount of material from their immediate neighborhoods and become thick at the pattern edge and wider in feature size. In general, variations in pattern dimensions are unfavorable for process control. However, in this case, the changes in the exposed geometry are just opposite to those caused by the electron beam proximity effect. Therefore, by carefully controlling the parameters of the post-exposure bake, excellent proximity effect corrections have been obtained. (Edited author abstract) 10 refs.

## Dissolution

**078412 SOLVENT PENETRATION AND PHOTO-RESIST DISSOLUTION: A FLUORESCENCE QUENCHING AND INTERFEROMETRY STUDY.** A novel method, based upon fluorescence quenching measurements, is described for the study of the mechanistic details of solvent penetration into thin polymer films. Here poly(methyl methacrylate) (PMMA) labelled with phenanthrene (Phe) groups was coated as a film onto quartz disks. Diffusion of solvent (1:1 2-butanone/2-propanol) into the film was followed by a decrease in the fluorescence, while film dissolution was monitored simultaneously by laser interferometry. In the case of PMMA both processes occur at approximately the same rate and exhibit non-Fickian (relaxation-controlled) diffusion behavior. Correlating the results of these two experiments shows that, once the steady state is reached, the dissolution rate is controlled by the advance of the solvent front into the PMMA film. The 'transition layer,' an important dissolution parameter, increases its thickness from 50 to 90 nm during the plasticization stage of solvent penetration and maintains its thickness until the solvent front reaches the quartz substrate. (Edited author abstract) 21 refs.

**078413 SYNERGISTIC ENHANCEMENT OF DIRECT SYNCHROTRON RADIATION ETCHING OF A RESIST BY A LOW-ENERGY OXYGEN BEAM.** The effect of the simultaneous irradiation of a low-energy ion beam with synchrotron radiation (SR) was investigated. The purpose was the enhancement of the direct resist etching by SR. Although the removal by sputtering of the resist was observed due to the wide energy width of the ion beam used, it was confirmed that the net SR etching, which was estimated after subtraction of the sputtering contribution, increased about two times. Possibilities for the enhancement of this 'synergistic effect' induced by low-energy ion beam bombardment to improve the direct SR etching and make it more practical are also discussed. (Author abstract) 8 refs.

## Evaluation

**078414 COMPARISON OF STANDARD PHOTO-RESIST AND CONTRAST-ENHANCED PHOTO-RESIST PROCESS SENSITIVITIES.** Statistical experimental design techniques were used to make a systematic comparison between a standard photoresist process and a contrast-enhanced photoresist process. This approach allowed determination and comparison of process sensitivities and their dependence on process changes. The resist used in this study was HPR204, and the contrast-enhancement material was Altilith CEM 420. All substrates were exposed on a GCA 10X stepper with a 0.28NA, G-line lens. The results indicate that the contrast-enhanced process is less sensitive to focus and exposure dose variation, extends the effective working resolution of the exposure tool, and gives an increased sidewall angle in the final resist pattern, when compared to the standard resist process. (Edited author abstract) 17 refs.

## Fabrication

**078415 IDENTIFYING SURFACE CONTAMINATION ON PELICULIZED PHOTOMASKS.** Several users of pelliclized chrome masks have reported the appearance of particulate deposits on the masks under the pellicle. Efforts to identify the particulate material were undertaken as a first step toward understanding and eliminating the problem. A combination of various spectroscopic analyses with gas chromatography/mass spectrometry allowed specific identification of the material as 2,5-di-tert-pentylhydroquinone. Comparison of the IR and MS spectra of the contaminating material with the spectra obtained from known samples of the pure compound confirmed its identity. The source of this impurity was traced to an adhesive tape used for attaching the frame to the photomask.

## Focusing

**078416 CHARACTERIZATION OF LINEWIDTH VARIATION FOR SINGLE- AND MULTIPLE-LAYER RESIST SYSTEMS.** The advantages gained by the use of a multilayer resist system were examined by electrical linewidth measurements of polysilicon lines ranging in width from 0.7 to 1.0  $\mu\text{m}$ . Multilayer resist was compared to single-layer resist and quantitative data was obtained regarding the theoretical advantages of reduced reflectivity, improved planarity, and thinner imaging resist inherent to a multilayer resist system. Two different thicknesses of single-layer resist revealed that a thinner imaging layer resulted in improvements of up to 15% for linewidth variation and 35% for depth of focus. Reducing reflections from the substrate from 33% to 3.5% led to improvements of up to 30% in linewidth variation and depth of focus. Introduction of a particular type of topography under the polysilicon led to a worsened linewidth variation and depth of focus, by up to 30%. 11 refs.

**Materials** See Also POLYIMIDES—Applications; SEMI-CONDUCTING SILICON—Amorphous.

**078418 IMPROVED POSITIVE PHOTO-RESIST.** An improved positive photoresist has been formulated using a styrene-maleimide binder in place of the previously used methacrylates. Film toughness is markedly improved, and the resists can be developed in aqueous solvents with little or no organic assist. Second images can be created with essentially the same exposure-development cycle as the first images. (Author abstract) 3 refs.

Weigert, F.J. (DuPont, Wilmington, DE, USA); Proskow, S.; Mitchell, R.S. *J Imaging Sci* v 31 n 5 Sep-Oct 1987 p 223-225.

**078419 PLASMA-PROCESSED OBLIQUELY DE-POSITED Bi-Ge-Se AND Ag/Bi-Ge-Se FILMS AS RESIST MATERIALS.** Lithographic properties of photoexposed  $\text{Bi}_{10}\text{Ge}_{20}\text{Se}_{70}$  and  $\text{Ag/Bi}_{10}\text{Ge}_{20}\text{Se}_{70}$  films and hydrogen plasma exposed  $\text{Ag/Bi}_{10}\text{Ge}_{20}\text{Se}_{70}$  films have been investigated. The as-deposited films show a positive resist behavior on exposure to photons and the silver overlayers show a negative resist behavior on exposure to both photons and hydrogen plasma. The contrast values are 1.25 and 2.3 for photoexposed positive and negative resists, respectively, and 5.0 for plasma-exposed negative resist. The sensitivity is approximately  $10^{20}$  photons/cm<sup>2</sup> for the photoexposed positive and negative resists and  $10^{18}$  ions/cm<sup>2</sup> (0.11 C/cm<sup>2</sup>) for the plasma-exposed negative resist. (Author abstract) 26 refs.

**078420 WATER SOLUBLE POSITIVE-TYPE PHOTO-RESIST USING A PHOTOLYSIS OF IMINO SULFONATES.** Positive-type photoresists which can be developed with water are synthesized from the copolymerization of 9-fluorenylideneimino p-styrenesulfonate and 2-(dialkylamino)ethyl methacrylate. The photochemical properties of the polymers are studied. Poly(dialkylaminoethyl methacrylate) bearing imino sulfonate units were found to be a useful positive-type photoresist which can be developed with water. (Edited author abstract). 4 refs.

Shirai, Masamitsu (Univ of Osaka Prefecture, Sakai, Jpn); Katsuta, Nobuyuki; Tsunooka, Masahiro; Tanaka, Makoto; Nishijima, Kanji; Ishikawa, Katsukiyo. *Chem Express* v 3 n 7 Jul 1988 p 439-442.

**078421 NEW APPROACH TO HIGH TEMPERATURE PHOTO-RESISTS BASED ON STYRYL-PYRIDINIUM UNITS.** Four linear polyesters containing styrylpyridinium units were prepared from 2,6-bis(p-hydroxystyryl)pyridine and terephthalic acid, isophthalic acid, adipic acid, and sebacic acid, respectively. The polyesters are thermally stable in the 365 to 450°C range. The decomposition temperature is higher for aromatic polyesters, lower for their aliphatic analogs. The polyesters are photoreactive and crosslink on irradiation with UV. The crosslinking mechanism is 2 + 2 cycloaddition. The polyesters form protonated complexes with  $\text{CF}_3\text{COOH}$  which absorb at longer wavelengths and are also photoreactive. The quantum yield of the photoreaction and the relative photosensitivities of the polyesters and their complexes were determined. (Author abstract). 9 refs.

**Optical Properties** See COPOLYMERS—Synthesis.

## Optimization

**078424 THREE-DIMENSIONAL REISTS SHAPE SIMULATOR AND ITS APPLICATION TO SUBMICRON VLSI PROCESS.** A three-dimensional photoresist shape simulator has been developed for the submicron process. Using this simulator, it is possible to analyze and optimize the photoresist process using an arbitrary projector, photoresist, and developer. In this technique, considering the man-machine interface, the three-dimensional shape of the photoresist can be shown in a colorgraphic VDT and plotter. Comparing the result of the three-dimensional simulation using the contact hole pattern with that of the two-dimensional simulation, a discrepancy occurs in the dimension less than 1  $\mu$ m between the two techniques, and it has been found that three-dimensional simulation is necessary when the width and depth of the pattern are in the same order. Using the three-dimensional simulation, a resolution of 0.5  $\mu$ m cannot be achieved when the wavelength of the light source is 435.8 nm, the numerical aperture of the projection lens N.A. is 0.28, and the coherency  $\sigma$  is 0.7. However, such a resolution can be achieved by using the wavelength of the light source of 435.8 nm, N.A. of 0.42, and  $\sigma$  of 0.5. (Author abstract) 7 refs.

## Performance

**078425 IMPROVED PHOTORESIST TECHNOLOGY AVAILABLE IN EUROPE.** Major trends in the PWB industry and the requirements from the manufacturers to reduce reject rates at the imaging and chemical process stages have demanded a new generation of dry film photoresists. Details are given of the requirements laid down by the industry, how the dry film resist manufacturers have responded, and how the improved resist technology meets these demands. These latest products are available in Europe and resist improvements have been welcomed by the board manufacturers.

Newport, B.L. (OMI Int (GB) Ltd, Woking, Engl). *Circuit World* v 14 n 4 Jul 1988 p 21-22.

## Photochemical Reactions

**078426 RECIPROCITY FAILURE IN NOVOLAK/DIAZOQUINONE PHOTORESIST WITH 364-NM EXPOSURE.** Intensity-independent photobleaching (reciprocity failure) was observed when a film of novolak/diazoquinone photoresist was exposed at 364 and 351 nm in the intensity range 1 to 400 mW/cm<sup>2</sup>. It was found that a dark reaction can be observed for short times after turning off the light during a bleach. It is postulated that these effects are a result of the absorbance of the intermediate ketene, which may decay on the same time scale as the exposure time and hence introduce a non-photochemical time-dependent bleaching that couples with the photochemical bleaching to give reciprocity failure. The magnitude of the reciprocity failure is sufficient to have a significant detrimental effect on resolution and process control. Thus it is important not only to reduce the absorbance of the final product but also that of the intermediates. 14 refs.

**078427 SPIN-COATABLE INORGANIC RESISTS BASED ON NOVEL: PEROXOPOLYNOBOTUNGSTIC ACIDS FOR BILAYER LITHOGRAPHY.** New peroxopolyacids based on tungsten and niobium (Nb-HPA) were synthesized and investigated as negative inorganic resist materials for microlithography. Amorphous and microstructure-free thin films, obtained from their water-based solution using a conventional spin-coating technique, exhibited sensitivity to deep UV ( $D_{0.5} = 150$  mJ/cm<sup>2</sup>, Xe-Hg lamp), E-beam (10  $\mu$ C/cm<sup>2</sup>, 30 kV) and x-ray (120 mJ/cm<sup>2</sup>, Mo L). The O<sub>2</sub>-RIE resistivity of Nb-NPA film was found to be 50 times greater than that of polyimide resin (PIQ resin). Patterns as fine as 0.2  $\mu$ m with an aspect ratio of 7.5 were successfully fabricated through the E-beam bilayer process in which the bottom layer was PIQ (1.5  $\mu$ m thickness) and the top, Nb-HPA (0.1  $\mu$ m). (Author abstract) 10 refs.

**078428 EMISSION SPECTRA OF AN AZIDE PHOTORESIST INITIATOR AND EXPOSURE RECIPROCITY.** From the excitation and emission spectra presented, it can be concluded that the assumption of the broad absorption band for negative photoresists being due to a single transition is not valid. This absorption band is composed of transitions between discrete states one of which, <sup>3</sup>nπ\*, is attributed to be narrow. De-excitation from the excited states of the broad band does not occur by a cascading mechanism that includes the <sup>3</sup>nπ\* state, if these discrete states are narrow, similar to the observed state, it may also be concluded that the lifetimes in these states are consisted of a broad single state only. 13 refs.

## Spectroscopic Analysis

**078429 CHARACTERIZATION OF ION-IMPLANTED PHOTORESIST FILMS BY FOURIER TRANSFORM INFRARED SPECTROSCOPY.** Positive photoresist was characterized by Fourier Transform infrared (FTIR) spectroscopy after high dose, high power ion implantation. The concentration of individual components in the resist such as the photosensitizer and organic C-H bonds were determined independently by examining the integrated absorbances at the corresponding infrared absorption peaks: 2040-2200 cm<sup>-1</sup> for the sensitizer, and 2820-2995 cm<sup>-1</sup> for the stretch of C-H bonds. Degradation of the sensitizer was found to be largely due to the elevated wafer temperature which is dependent on the heat generated by the ion implant and the cooling mechanism of the implanter. The thickness of the carbonized layer can be estimated by the loss of C-H bonds, which is in agreement with SEM results. (Edited author abstract) 8 refs.

**078430 CHARACTERIZATION OF THIN-FILM NEGATIVE RESIST VIA PHOTO-FT-IR.** Negative thin-film photoresists are used extensively in the circuitization of metalized substrates. Frequently questions regarding resist performance and reproducibility arise which require extensive functional evaluation. The analysis of the exposure (intensity, dose, and wavelength) and temperature effects typically requires the incremental analysis of a large matrix of samples. Photoreactions occurring in

these resists can be conveniently monitored by FT-IR and correlated with functional performance. We have developed hardware and software accessories for an FT-IR spectrometer which allows spectroscopic analysis of photoresists during exposure to UV light. The utility of the Photo-FT-IR is demonstrated by a report of the photoreaction of two typical negative photoresists as a function of intensity and wavelength. We also report on the thermal stability of these two resist systems. (Author abstract) 7 refs.

## Synthesis

**078431 PREPARATION OF PHOTORESIST POLYMER BY A PHOTOREACTIVE MONOMER CONTAINING N,N-DIETHYLDITHIOCARBAMATE GROUP.** A novel photosensitive monomer with a pendant photoreactive diethyldithiocarbamoyl group, VEDC, was synthesized and copolymerized with some vinyl monomers by AIBN. The copolymers obtained have efficient photocrosslinking abilities, and are thermally stable. Therefore, there was no loss of dithiocarbamoyl group during radical polymerization, and the polymerization proceeded through vinyl group, but photosensitivity of the polymer was not. Water-soluble photoreactive copolymers, VBDC with AAm or MA, were also prepared. The mechanism of photocrosslinking was studied by photodecomposition of benzyl N,N-diethyldithiocarbamate, and the result that the decreases of sulfur content clearly related to photocrosslinking points was also obtained. (Edited author abstract) 12 refs.

**078435 EXPERIMENTAL VERIFICATION OF SUPERLINEAR DEPENDENCE OF THE PHOTOCURRENT OF A SILICON PHOTOVOLTAIC CELL ON THE LEVEL OF ILLUMINATION.** The authors investigated silicon photovoltaic cells with an isotype back junction in conditions of concentrated radiation. We used a concentrating device based on a one-meter concentrator with an automatic system for tracking the sun in two planes. To determine the photocurrents ( $I_{ph}$ ) of two PV cells, we measured their volt-ampere characteristics (VAC) in a photodiode regime over a wide range of illumination: from 1 to 200 solar constants (SC). The degree of concentration of the luminous flux (K) was determined according to the ratio of photocurrents from the PV cells made of GaAs. The results are presented in the form of the dependence of C on K. Beginning with K=20, a superlinear dependence of  $I_{ph}$  on the level of illumination is manifested. With an increase in K, C rises, and at K=40 saturation of C sets in, which is equal to 1.4. 3 refs.

**078436 ELECTROPLATED  $Cu_2S$ -CdS PHOTOVOLTAIC CELLS.** The results of a reliable electroplating method for the formation of the chalcocite ( $Cu_2S$ ) phase of copper sulphide on thin film CdS substrates are reported. The problem of the stability of the CdS- $Cu_2S$  photovoltaic devices so formed is addressed by studying the combined effect of the substrate on which the CdS is deposited and the ambient used when annealing. Steady state photocapacitance measurements show that the most stable cells, which are fabricated on Ag/Cr substrates, exhibit a deep electron trap in the CdS some 0.95 eV below the conduction band. It is concluded that this trap inhibits the in-diffusion of copper into the CdS during annealing of the CdS- $Cu_2S$  cell and can be attributed to a complex associate formed between silver and oxygen. (Author abstract) 24 refs.

**078437 DYNAMIC OPTIMAL COUPLING OF A PHOTOVOLTAIC POWER SYSTEM AND INDUCTION MOTOR.** In this paper a new method for optimum matching the induction motor with varying mechanical load to a solar photovoltaic power system (PV) is presented. This method utilizes a maximum mechanical energy supply to the load by means of switching procedures and other devices. Dc/ac inverter has been used to change the SCA output to ac power. Harmonic analysis is applied on the inverter output wave. Then the suitable ac-filter is designed to improve the waveform output from the used inverter. New hourly series-parallel solar cell modules connections (SMMC) are proposed and applied. The impact of induction motor starting on the optimum SCA size and on the energy cost figure is discussed in detail. (Author abstract) 8 refs.

**078438 LIGHT-POWERED ARCHITECTURE.** Photovoltaics (PVs) are semiconductors that generate

electricity when exposed to light. In the family of semiconductor technology, photovoltaics are kin to simple semiconductor switches, the key part of all microprocessors. In the US, including Alaska and Hawaii, PVs now electrify a few thousand remotely located homes and thousands of remote facilities such as microwave stations, railroad signals, and harbor navigation lights. Compared to all other forms of energy technology, PVs are uniquely modular. One 4-ft-sq PV module, about an inch thick, can provide basic power to a remote homesite, boat, or telephone system. The same module, mass-produced in the thousands and installed on racks to track the sun, becomes a utility-scale generating station. With PVs, it is technically feasible to design a building with no utility connections except water, sewage, and possibly gas.

**078441 CONSEQUENCES OF MISFIT AND THREADING DISLOCATIONS ON PV DEVICE DESIGN.** The relative weights of surface recombination, misfit dislocation density and threading dislocation density in the performance of a photovoltaic device are ascertained in the generation-recombination operating limit of a planar HgCdTe double layer heterostructure. In this limit, surface recombination is found to be much less important than the dislocations, while the balance between misfit and threading dislocations is determined by the relative size of the average misfit segment length and the device lateral dimension. ### Energy Utilization

**078445 FEASIBILITY STUDY OF PHOTOVOLTAIC-FUEL CELL HYBRID ENERGY SYSTEM.** The concept and feasibility study results of applying fuel cells to provide operational support to photovoltaic (PV) arrays are presented. Through simulation using actual data, it is shown that it is feasible to use fuel cells in coordination with PV to meet variable loads to either utility or stand-alone applications. The dynamic response required of the fuel cell to support the hybrid operation is found to be well within the capabilities of the prototype designs that have been tested in the United States and Japan. The hybrid operation overcomes the intermittency problem inherent with PV and makes possible novel applications for the fuel cell technology. 17 refs.

### Manufacture

**078446 CHARACTERIZATION AND CONTROL OF PHOSPHINE HAZARDS IN PHOTOVOLTAIC CELL MANUFACTURE.** Phosphine ( $PH_3$ ) is a highly toxic and flammable gas used in photovoltaic cell manufacturing. Its use can present serious occupational and public health hazards if appropriate prevention and control options are not implemented. This report reviews technologies for controlling  $PH_3$  emissions during routine operation and accidents, hazard prevention options, and emergency preparedness and response strategies. Routine  $PH_3$  emissions can be controlled by using carbon adsorption for very low concentrations and thermal incineration or multistage chemical scrubbing for higher concentra-

tions. Massive accidental releases are difficult to control and could jeopardize the life and health of persons living near a plant. Options for preventing or minimizing accidental releases (e.g. flow-restricting valves) need to be implemented to reduce such risks. Industry and community emergency response planning can further reduce the magnitude of these hazards. (Edited author abstract) 14 refs.

**078448 LOW TEMPERATURE CHEMICAL PRECIPITATION AND VAPOR DEPOSITION OF  $\text{Sn}_2\text{S}$  THIN FILMS.** Films of gray-black  $\text{Sn}_{1-x}\text{S}$  ( $E_g \approx 1.0$ -1.3 eV), brown  $\text{Sn}_{2-x}\text{S}_3$  ( $E_g \approx 1.6$ -1.9 eV), and/or  $\text{SnS}_{2-x}$  ( $E_g \approx 2.1$ -2.3 eV) were deposited onto nonconductive substrates by (i) an 'electroless' chemical precipitation mechanism in organic acid/ $\text{H}_2\text{O}$  baths of  $\text{SnCl}_2$ , S, and  $\text{Sn(II)}$ -complexing agents and/or (ii) a novel, above-solution CVD mechanism involving condensation and reaction of Sn and S species such as  $\text{SnCl}_4$  and  $\text{H}_2\text{S}$ .  $\text{H}_2\text{O}$  and complexing agent (potassium gluconate or tartaric acid) concentrations critically affect film stoichiometry due to their 'freeing' (with acid ionization) or chelating of the  $\text{Sn(II)}$ . A surface area-minimizing  $\text{Sn(II,IV)}\text{-S(II)}$  exchange reaction is postulated to explain slow transfer of  $\text{Sn}_2\text{S}$  deposit/precipitate to smooth surfaces. (Edited author abstract) 17 refs.

**078450 SPECTRAL COSENSITIZATION IN PHTHALOCYANINE-PORPHYRIN PHOTOELECTROCHEMICAL CELLS.** An organic multilayer photoelectrochemical cell was fabricated by sequential vacuum deposition of hydroxylaluminum phthalocyanine (PcA-I-OH) and hydroxylaluminum tetraphenylporphyrin (TPPAIOH). Absorption and action spectra of the NESA/PCAI-OH/TPPAIOH/ $\text{I}_3^-/\text{I}^-$ /Pt cell cover the entire visible spectrum up to 900 nm. In the reverse deposition sequence, only NESA/TPPAIOH/PCAI-OH/ $\text{I}_3^-/\text{I}^-$ /Pt photoelectrochemical cell with very thin organic layers showed a sensitization effect. The sensitization effects are probably due to the porosity of the organic thin films, allowing the contact of the electrolyte with each semiconductor. (Author abstract) 17 refs.

Perrier, Gerard (INRS-Energie, Varennes, Que, Can); Gauthier, Rosanne; Dao, Le H. *J Electrochem Soc* v 135

n 3 Mar 1988 p 598-602.

**078451 PHOTOVOLTAIC EFFECT BASED ON WET POLY(VINYL ALCOHOL)/MERCYANINE DYE JUNCTION.** The sandwich cell, Au/wet poly(vinyl alcohol) (PVA)/merocyanine (MD)/Au, based on the PVA/MD junction exhibited photovoltaic and rectifying effects. Forward dark current from the MD/Au electrode to the counter PVA/Au electrode through the cell was observed. The Au/MD electrode showed a positive photovoltage with respect to the PVA/Au electrode regardless of the direction of the incident light. It was suggested that a heterojunction barrier similar to the Schottky type formed at polymer/dye interface was responsible for the photo charge separation. (Author abstract) 8 refs.

Uehara, Kaku (Univ of Osaka Prefecture, Sakai, Jpn); Takagishi, Kenji; Tanaka, Makoto. *J Appl Polym Sci* v 35 n 7 May 20 1988 p 1759-1767.

**078452 SOLAR POWER COMES DOWN TO EARTH.** An American company, Chronar Corporation, was set up in 1975 with the aim of developing a commercial, low-cost photovoltaic technology. The results of these efforts have recently come to fruition with the introduction of a series of commercial products and a major generating installation set up in the US. The basic structure of the photovoltaic panel comprises a thin layer of silicon semiconductor sandwiched between two electrodes, the whole being supported on a glass substrate. The back electrode that faces the light source is a transparent layer of tin(IV) oxide. While there are numerous ways of obtaining tin oxide coatings, the method chosen is atmospheric pressure chemical vapor deposition (APCVD) using equipment specially developed for this technique. 3 refs.

## Mathematical Models

**078453 GENERALIZED CAPACITY FACTORS FOR GRID-INTERTIE SOLAR PHOTOVOLTAIC SYSTEMS.** We present a simple calculation and graphical procedure for direct determination of the annual capacity factor of no-storage grid-intertie photovoltaic systems. This is applicable to the principal solar collector types and to a wide range of climates. This method provides 'translation equations' for predicting both instantaneous power output (under any specified test conditions) and long-term average power output of photovoltaic modules from instantaneous measurements. Such a procedure, which we validate for one site only, should enable a designer to make accurate preliminary assessments concerning the suitability of potential sites and solar collector types by simple analytic calculations or, equivalently, by reading points off the graphs presented herein. (Author abstract) 13 refs.

**078454 THREE-DIMENSIONAL ANALYTICAL SIMULATION OF SELF- AND CROSS-RESPONSIVITIES OF PHOTOVOLTAIC DETECTOR ARRAYS.** The degradation of spatial resolution and sensitivity due to lateral transport is modeled using a novel 3-D analytical solution of the continuity equation. Three detector structures are investigated: the semi-infinite substrate, the perfectly collecting, and the perfectly reflecting backside. The front and rear illuminations are treated. The calculated results for the 3-D case deviate fundamentally from those predicted by the 1-D model. The 3-D model explains the reduced quantum efficiency of small-area detectors and predicts the limited effect that diffusion length has on self-responsivity and cutoff wavelength. The calculated spectral responses fit data measured on InSb and HgCdTe test arrays extremely well. 28 refs.

## Research

**078458 OPENING THE DOOR FOR UTILITY PHOTOVOLTAICS.** EPRI's point-contact photovoltaic cell has achieved the world's highest conversion efficiencies in a laboratory environment. But can such devices be economically mass-produced for utility-scale applications? Researchers, microcircuit manufacturers, and utility investors are betting that they can. This paper discusses the physics of a point-contact cell, the materials used for its development, packaging the solar concentrator and the performance of central station photovoltaic plant. 9 refs.

**Testing**

**078464 NEW MEASURED Z-VALUES AND THEIR EFFECTS ON THE VOLTAGE EFFICIENCY OF VCl<sub>3</sub>-THIONINE PHOTO GALVANIC SYSTEM.** In this paper, new Z-values for twenty pure solvents and their aqueous mixtures at 25%, 50% and 75% water by volume have been determined by using 1-methyl-4-carbomethoxy-pyridinium iodide at room temperature. The effect of pure solvents and their water mixtures on the VCl<sub>3</sub>-Thionine photogalvanic system has been investigated. The voltage efficiency of the photogalvanic cell was determined for each solution and was related with the Z-values. The results show that the highest voltage efficiency was obtained with acetonitrile and acetone and aqueous mixtures of these two solvents. (Edited author abstract) 27 refs.

**078465 PHOTOVOLTAIC COMPONENTS AND SYSTEMS TESTING: A PROPOSED PROGRAM.** Since the application of PV power systems has rapidly increased in Indonesia, and hence the need for information on PV components, subsystems and systems, a facility and capability for testing their performance need to be established. This facility is being developed to ensure that the PV components, subsystems and systems used in Indonesia meet the established standards and specifications. 6 refs.

**Thermal Effects**

**078466 MIRAGE EFFECT IN PHOTOELECTROCHEMISTRY.** The mirage effect can be used to characterize the power dissipation mechanisms of solid-state photovoltaic cells. The present work discusses the mirage effect in a photoelectrochemical cell, with the specific purpose of demonstrating that both thermal and concentration waves contribute to the beam deflection experiments and that the two effects can be separated only with a careful choice of the experimental conditions. 4 refs.

**078467 VOLTAIC CELLS OF (Zn<sub>1-x</sub>Cu<sub>x</sub>)<sub>2</sub>O<sub>3</sub> THIN FILMS DEPOSITED BY R.F. SPUTTERING.** The growth of (Zn<sub>28-42</sub>Cu<sub>39-25</sub>)O<sub>33</sub> thin films deposited by r.f. sputtering was studied. Voltaic elements with an ITO/(Zn, Cu)O/Al structure (where ITO is indium tin oxide) were fabricated. The open-circuit voltage and short-circuit current at temperatures of 0-45°C were 0.5-1.25 V and 0.3-1.5  $\mu$ A cm<sup>-2</sup> respectively. The composition of the films was studied by Auger analysis. (Author abstract) 5 refs.

**078468 CELLE FOTOVOLTAICHE A FILM SOTTILE DI SILICIO AMORFO. [Thin Film Amorphous Silicon Photovoltaic Cells].** Thin film amorphous silicon photovoltaic cells promise efficient conversion of solar energy and production costs capable of generating, in medium-long term, economically competitive electric power. Characteristics of the material require structures of

the device that are different from those used in the crystalline material. The principles of operation of these structures, the configurations most frequently used, the factors limiting the performance, and some solutions to improve efficiency and stability are analyzed. The structure and the process of fabrication of amorphous integrated models are finally briefly described. (Translated author abstract). 6 Refs. In Italian.

**Transport Properties**

**078470 ELECTRICAL TRANSPORT PROPERTIES OF POLYCRYSTALLINE CuInSe<sub>2</sub> FILMS.** Electrical conductivity and Hall effect measurements were made on CuInSe<sub>2</sub> films prepared by coevaporation. The films were characterized as grown and after annealing in a 90 percent N<sub>2</sub> + 10 percent H<sub>2</sub> atmosphere. The hole density was in the interval 10<sup>13</sup>-10<sup>19</sup> cm<sup>-3</sup>. The conductivity activation energy ranged from 0.03 to 0.5 eV in the range 300-400 K. The hole density decreased and the mobility increased with the annealing process. Grain boundary trapping models were considered in the analysis of the results. Compensation effects, partial or total depletion of the grains, and variations in the compensation ratio and the trap density with annealing were observed. (Author abstract). 28 Refs.

**078471 PHOTOVOLTAIC EFFECT OF AN INSULATING POLYMER-HYBRIDIZED p-Si SOLAR CELL.** The authors report on a photovoltaic cell in which a p-Si electrode is hybridized with an insulating polymer. The well-known photovoltaic effect of a MIS (Metal-Insulator-Semiconductor) cell is based on the Schottky barrier and therefore the cell represents rectification. The photovoltaic cell has a structure similar to that of a MIS cell but shows peculiar current-voltage (I-V) characteristics. 6 refs.

**078472 ASSOZIATIONSVERHALTEN UND DIPOLMOMENTE VON TETRA(N-BUTYL)-AMMONIUMPERTECHNETAT UND TETRA(N-BUTYL)AMMONIUMPERCHLORAT IN BENZOL.** [Association Behavior and Dipole Moments of Tetra-n-butylammonium Pertechnetate and Tetra-n-butylammonium perchlorate in Benzene]. At very low concentrations tetra-n-butylammonium pertechnetate and tetra-n-butylammonium perchlorate from ion pairs in benzene solutions. At room temperature, formation of dimers and larger aggregates begins to occur at concentrations of  $10^{-5}$  mol/l. This behavior has been investigated quantitatively by the determination of the molecular weight in the case of the perchlorate salt, and by the concentration-dependence of the pertechnetate phase equilibrium between water and benzene. It is demonstrated that  $\text{Bu}_4\text{NTO}_4$ -dimers and larger aggregates have no apparent dipole moment. (Edited author abstract) In German. 17 refs.

## Adsorption

**078473 ELECTRONIC STRUCTURE OF CHEMISORBED FORMATE LAYERS ON COPPER SURFACES.** Much can be learned about the bonding of adsorbates on transition- and noble-metal surfaces from calculations of the electronic structure of chemisorbed overlayers on thin slabs. We demonstrate the technique here applied to formate on copper (100) and (110) surfaces. After consideration of the molecular orbitals of the free formic acid and formate radicals, we show the changes in electronic structure accompanying chemisorption in the various potential surface sites suggested by LEED, X-ray absorption, and vibrational spectra. For both atop and bridge sites occupied adsorbate bands fall into three main groups, 12 ( $4a_1$ ), 9 ( $5a_1$ ,  $3b_1$ ,  $1b_2$ ) and 5 ( $1a_2$ ,  $6a_1$  and  $4b_1$ ) eV below  $E_F$ , close to the peaks seen in photoemission studies; the closest agreement is probably for the formate in bridge sites, oriented along with its oxygen atoms almost directly above surface copper atoms. (Author abstract) 25 refs.

## Coagulation

**078474 NUMERICAL EVALUATION OF SELF-PRESERVING SPECTRA IN SMOLUCHOWSKI'S COAGULATION THEORY.** The cluster size distribution  $c_k(t)$  in aggregation and coagulation phenomena for large cluster sizes  $k$  and large times  $t$  approaches a scaling form of self-preserving spectrum  $c_k(t) \approx s^{-2}(\phi(k/s))$ , where  $s(t)$  is the mean cluster size. In a mean field approach the scaling form  $\phi(x)$  is described by a nonlinear integrodifferential equation, obtained from Smoluchowski's coagulation equation. To verify some theoretical predictions and to provide quantitative information on the scaling form we develop a fixed point method to determine numerical solutions of this equation for aggregation rate constants  $K(s,y) = \alpha y^\beta + \gamma x^\beta$  with  $\alpha > \beta$  and  $\beta < 0$  (class III models), where  $\phi(x)$  is bell-shaped, and we study the crossover to class II models ( $\beta = 0$ ), where  $\phi(x) \approx x^{-\tau}$  as  $x \rightarrow 0$ , and calculate the exponent  $\tau$ . (Author abstract) 14 refs.

## Computer Aided Analysis

**078475 COMPUTER-AIDED FORMULATION.** Currently available on the market are new, low-cost personal computer (PC) software packages that can considerably reduce the theoretical work of physical properties analysis and of formulating for specific target properties. A software system previously developed for smaller paint manufacturers can computerize batch ticketing, cost analysis, physical properties analyses, inventory, and MSDs (material safety data sheets).

## Flocculation

**078476 HYDROPHOBIC FLOCCULATION.** Aggregation and flocculation of dispersed clays and silica by cationic polyelectrolytes depends upon the nature of the solids and the solution properties of the polyelectrolytes. The energy required for the formation of aggregates or flocs is provided by hydrophobic interactions between polymer molecules adsorbed onto adjacent particles. Polymer performance is directly related to the mass of polymer which can be added to the system before the overtreatment regime is reached. (Author abstract) 31 refs.

**078477 EQUILIBRIUM SHAPES OF LIQUID BRIDGES UNDER GRAVITY: SYMMETRY BREAKING AND IMPERFECT BIFURCATIONS OF TWO-DIMENSIONAL BRIDGES.** The equilibrium shapes of a two-dimensional liquid bridge are constructed via a shooting and continuation numerical solution of the Laplace-Young equation which focuses on the bifurcation point of the solution branches. With the introduction of gravitational effects, this codimension 5 singularity is retained although the critical contact angle decreases slightly below  $90^\circ$  as one increases the difference between the interior and the exterior densities. However, when a slight tilt angle is introduced to the bridge, the maximum pressure singularity degenerates into two turning points (folds) and the solution branches are isolated from each other. This indicates that hysteretic jumps in the surface curvature and excess pressure exist with respect to changes in diameter/length ratio or liquid volume. Our numerical solution also reveals the existence of a maximum bridge volume that can be sustained by a nonneutrally buoyant bridge. No equilibrium shapes, symmetric or asymmetric, exist for bridge volumes beyond this critical value. (Edited author abstract) 19 refs.

**078479 SIMPLE MODEL FOR SUSTAINED OSCILLATIONS IN ISOTHERMAL BRANCHED-CHAIN OR AUTOCATALYTIC REACTIONS IN A WELL-STIRRED OPEN SYSTEM. III MULTIPLE STATIONARY STATES AND HOPF BIFURCATIONS.** A model is proposed for autocatalytic or branched-chain chemical systems, including some aspects of the oxidations of hydrogen or of carbon monoxide. Similar rate laws may arise in biochemical situations. The important parameters for this system are: the relative concentration of A and B in the inflow; the relative rates of reactions (1) and (2); the mean residence time and the saturation term. The system shows multiple stationary states. Sustained oscillatory reaction is also possible. This begins at Hopf bifurcation points. Degenerate bifurcations, of different types, have also been located, and tracked through the parameter space by numerical path-following techniques developed during this investigation. ## Spectroscopic Analysis

**078480 EXPERIENCE IN USE OF SYNCHROTRON RADIATION IN SOLID STATE CHEMISTRY STUDIES.** The characteristics of chemical reactions in solids - (1), local process, (2) high velocity, (3) nuclei formation in the crystal volume - makes special methods of investigation necessary. In this work it is shown that investigations of structural transformation which accompany chemical reactions proceeding at a high rate in local regions either in the volume, or on the crystal surface, are possible due to the unique peculiarities of synchrotron radiation. (Author abstract) 6 refs.

**078481 ORIGIN OF LIFE AND PHYSICS: DIVERSIFIED MICROSTRUCTURE - INDUCEMENT TO FORM INFORMATION-CARRYING AND KNOWLEDGE-ACCUMULATING SYSTEMS.** The process leading to the origin and evolution of life is caused by the presence of distinct physical and chemical conditions at a distinct location in the universe. A specified system originates and evolves under the continuous influence of a complex operational environment. The system develops toward increasing independence of the original environment by becoming increasingly complex. Modeling a detailed scenario consisting of a sequence of reasonable physico-chemical steps is essential in rationalizing the phenomenon. The basic process, accumulation of knowledge by continuously testing environmental properties, is intimately related to the measuring process in physics. Evolution is a physical process, and this process leads to man developing physics. Thus physics appears to be self-consistent - the basis and consequence of evolution. The physics-producing system is considered to be a measuring and information-processing device based upon the mechanism which operates in the origin and evolution of life. (Author abstract) 27 refs.

**078482 SPECIFICATION OF PHYSICAL ATTRIBUTE INFORMATION FOR ENGINEERING ANALYSIS.** This paper addresses the issue of specifying the functional information beyond that of the geometric domain of the object needed to qualify a problem in mathematical physics for which an engineering analysis is to be performed. A generalized geometry-based approach for the specification of this information is presented. This information, plus the domain definition to which it is tied, represents the complete specification of the problem to be analyzed. (Author abstract). 18 Refs.

**078483 ION BEAM INDUCED ATOMIC MIXING IN Ti/SiC.** The effects of 100 keV  $N_2^+$  and  $Ar^+$  ion implantation on atomic mixing and the hardness in 400 Å Ti deposited SiC were investigated by means of Monte Carlo simulation, He backscattering, Auger electron spectroscopy, and Vickers indentation method. It was shown that the carbon concentration near the surface was increased remarkably by  $N_2^+$  ion implantation at 1000°C, and those C atoms formed TiC. The experimental results far exceed the results obtained by the Monte Carlo simulation based on binary collision model. It was concluded that the C atoms, which originated from lattice sites in SiC by collision cascades, would migrate to the upper Ti layer by radiation enhanced thermal diffusion and react with Ti atoms. (Author abstract) 35 refs.

**078484 PHYSICAL MEANING OF NONELECTROMAGNETIC FIELDS IN A SPECIAL QUASICLASSICAL MODEL OF ATOMIC SYSTEMS.** It is assumed that to describe the quantum properties of an atomic system it is possible to introduce two nonelectromagnetic fields, one of which is described by the Schrödinger equation (the S-field), the other by the  $v$ -equation proposed by B.N. Rodimov (the K-field). Beginning with

the basic goal of the article, i.e., the construction of a quasiclassical model of an atomic system which details its inner structure, equations are obtained which determine the physical meaning of the K-field, and it is shown that it is not possible to construct analogous equations for the S-field. (Author abstract) 4 refs.

Korotchenko, F.B. (S.M. Kirov Polytechnical Inst, Tomsk, USSR). *Sov Phys J* v 30 n 3 Mar 1987 p 207-209.

**078485 RESTRUCTURING OF THE ATOMIC CONDENSED STATE UNDER CONDITIONS OF AN INTENSE EXTERNAL FIELD.** The ensemble of restructurable potential contours, the analysis of which permits modeling of the atomic state restructuring, is introduced. The corresponding changes in the behavior of the collective mode spectrum is analyzed. The mutually dependent restructuring of single-atom and collective states is examined. The spatial dependence of the hydrodynamic variables is considered in the framework of a field approach. The interpretation of specific physical phenomena on the basis of the developed formalism concludes the study. 56 refs.

**078487 EXCITATION OF ATOMIC NUCLEI AND ATOMS BY RELATIVISTIC CHARGE PARTICLES BOUND IN A ONE-DIMENSIONAL POTENTIAL.** The process of exciting atoms and atomic nuclei by relativistic electrons and positrons bound in a one-dimensional potential is investigated theoretically. It is shown that a pole corresponding to the emergence of a virtual photon on a bulk surface occurs in the matrix interaction element under definite kinematic relationships. It is obtained that the probability of the excitation process depends on the lifetime of the level being excited, the virtual photon, and the charged particle in a definite energetic state. An estimate of the magnitude of the excitation section of low-lying nuclear states yields a value exceeding by several orders the section obtained for charge particles in the absence of a binding potential. (Author abstract) 8 refs.

**078488 ON THE USE OF E-r AND A-p IN PERTURBATION CALCULATIONS OF TRANSITION INTENSITIES FOR PARAMAGNETIC IONS IN SOLIDS.** Perturbation calculations of the probability amplitudes for electric dipole transitions, particularly the 'parity forbidden' transitions within the  $1N$  configuration of paramagnetic ions in solids, are discussed. In general, the same results are obtained for the A-p and E-r forms of the atom-radiation interaction only if gauge invariance is properly accounted for. (Author abstract) 20 refs.

**078489 INFLUENCE OF INITIAL CONDITIONS ON SQUEEZING AND ANTI-BUNCHING IN THE JAYNES-CUMMINGS MODEL.** We have carried out a detailed investigation of squeezing and anti-bunching in the Jaynes-Cummings model, thereby extending the earlier work of Meystre and Zubairy. Analytic criteria are formulated relating the initial states of atom and field to the tendency of the field to undergo squeezing or anti-bunching when the atom enters the cavity. Some

interesting connections are established between atomic squeezing and field squeezing/anti-bunching. Using the initial conditions suggested by our criteria, we explore the generation of non-classical states of the cavity field. The relationship of our work to other recent work on squeezing and anti-bunching in the Jaynes-Cummings model is discussed. (Author abstract) 27 refs.

**078493 STARK-BROADENING OF Ar I LINES.** The half-width and shift of some Stark-broadened Ar I lines are measured using a highly-stabilized argon arc at different electron densities. The relation of the ratio of the half-width over the plasma electron density as a function of the electron density itself, for the isolated argon line, 4300 Å, shows an excellent agreement with the theory. This argon line may therefore be used for the accurate determination of the electron density in argon plasma sources. The line profile is analysed and discussed. (Author abstract). 14 Refs.

**078494 THEORY OF COUPLING OF ELECTRONIC SYSTEMS: EXPERIMENTAL STRUCTURES USING ADVANCED LITHOGRAPHIC TECHNIQUES.** This paper focuses on the physics of disorder-induced localization and the important role of advanced material microfabrication technology for realizing novel microstructures as physical models. Present and future microfabrication capabilities for tailoring materials in the submicron and ultramicroscale range offer the opportunity to fabricate controllable physical models, approaching atomic scale, for the fundamental study of coupling of electronic systems and the effect of dimensionality on transport properties. These physical models will require the ingenious exploitation of advanced lithographic/patterning techniques for controlling lateral dimensions, particularly if this is combined with advanced

vapor or molecular beam deposition technique for controlling vertical dimensions. The type of studies discussed here has great significance in understanding and designing highly-dense very large-scale/ultra large-scale integrated (VLSI/ULSI) circuits and interconnecting-lines-dominated neural network IC systems, as well as in the studies of the scaling theories of localization. It is expected that these studies will lead to the design of novel device concepts. (Author abstract) 39 refs.

**078496 IRREGULARITIES IN THE DIFFERENTIAL AND INTEGRAL CROSS SECTIONS FIGURES FOR ION-ATOM COLLISIONS IN THE PLANE-WAVE BORN APPROXIMATION.** We discuss the generalized oscillator strength (GOS), a fundamental physical quantity that represents the response of an atom to the interaction with a charge. The GOS is related to the differential cross section for excitation in ion-atom collisions in the plane-wave Born approximation (PWBA). The GOS for a particular transition is a function of the momentum transferred from the relative motion to the atom. Approximate scaling of the GOS is sometimes found along an isoelectronic sequence, but is not found for those cases we have studied for which the GOS has a minimum. Two different mechanisms produce minima of the GOS; one is due essentially to nodes of one-electron radial wave functions, and the other is an effect of the configuration interaction that introduces an avoided crossing of energy levels plotted against the nuclear charge. A minimum of the GOS sometimes leads to a double-maximum structure of the integral cross section for ion-atom collisions in the PWBA, though one usually expects the PWBA to produce only one maximum. (Author abstract) 15 refs.

**078497 ATOMIC LIFETIME MEASUREMENTS USING RECOIL IONS.** Recoil ions are the secondary ions produced in energetic collisions of highly-charged heavy ions with atoms. The advantages and problems of using recoil ions for atomic lifetime measurements are outlined. Three types of experiments are discussed: a) pulsed primary ion beam and electronic lifetime measurement (in the ns range) of ions inside the target gas; b) time-of-flight measurements with position-sensitive detection on beams of recoil ions extracted from the production target (sub- $\mu$ s range); and c) external trapping of charge-state analysed recoil ions (up to ms). (Edited author abstract) 36 refs.

**078498 FINITE ELEMENTS IN PHYSICS, PROCEEDINGS OF THE 1ST EUROPEAN GRADUATE**

**SUMMER COURSE ON COMPUTATIONAL PHYSICS.** This publication contains 11 papers by various authors dealing with finite elements in physics. Major topics covered are: basic course in finite element methods (FEM), FEM to solve the Navier-Stokes equations, hyperbolic equations, Schrodinger equations; MHD analysis, plasma physics; material science; turbulence; solution of matrix problems and treatment of nonlinear partial differential equations by a continuation method. All papers are abstracted and indexed separately. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10544 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**078499 DEVELOPMENT OF SEVERAL OHP EQUIPMENT OF PHYSICS USING MOIRE PATTERNS.** This paper reports on several simple OHP equipments for education using Moire patterns. The first equipment is concerned with centrifugal waves. The Moire pattern is produced by superposing two specified patterns composed of straight lines and curves. The two patterns are determined as functions of the wave propagation velocity. The second is the fluid model used in demonstrating such notions in vector analysis as divergence. The spiral traveling wave is simulated using the reverse Moire, which is a counterpart of the Moire technique. The third is the equipment to simulate the electric lines of force produced by a pair of point charges and is used in teaching electromagnetics. The patterns are designed also for easy understanding of Moire phenomena. (Edited author abstract) 9 refs.

**078500 COMPUTERIZED PENDULUM EXPERIMENT FOR THE INTRODUCTORY PHYSICS LABORATORY.** A Commodore 64 micro computer is used to control a simple pendulum experiment. The computer is interfaced to an interruptable light beam. It measures the pendulum parameters with good accuracy. The experiment is organized in three parts: (i) Tutorial: The student works through a tutorial based on an animated pendulum in preparation for the real experiment. (ii) Experiment (a): The student measures the pendulum parameters using conventional techniques. The computer constantly supervises the experiment and points out mistakes to the student. (iii) Experiment (b): The student uses the computer as an electronic measuring device to examine the relationship between period and amplitude. (Author abstract) 4 refs.

**078501 A-RELATION OF THE DIFFERENTIAL CROSS SECTION OF PHOTOPRODUCTION OF  $\pi^+$ -MESONS IN NUCLEI AT LOW ANGLES IN A RANGE OF  $P_{33}$ -RESONANCE.** Data are cited about the A-relation of the differential cross section of photoproduction of  $\pi^+$ -mesons in nuclei of  $^6\text{Li}$ ,  $^{12}\text{C}$ ,  $^{27}\text{Al}$ , Cu, and Cd (Cu, Cd - a natural mixture of isotopes) for a medium angle of meson escape of approximately  $10^\circ$  in c.m.s. (center of mass system) in an energy range of approximately 300-500 MeV. It is shown that the index of the A-relation is greatly changed with consideration of the difference in the measured points of the form factors of the nuclei and the meson escape angles. (Author abstract) 4 refs.

**078504 ENERGY RELATION OF THE TOTAL CROSS SECTIONS OF STRONG INELASTIC INTERACTION IN NUCLEAR-NUCLEAR COLLISIONS BASED ON A MODEL OF QUARK-GLUON JETS.** The total cross sections of strong inelastic interaction are calculated and their parametrization is acquired for a number of nuclei which interact with uranium and a nuclear photoemulsion up to values of the Lorentz factor of  $\gamma \approx 10^6-10^7$ . (Author abstract) 5 refs.

Goryachev, B.I.; Lin'kova, N.V. *Sov Phys Lebedev Inst Rep* n 2 1987 p 28-31.

**078505 INFLUENCE OF ELECTROSPALLATION OF RELATIVISTIC NUCLEI ON THEIR MEAN FREE PATH WITH RESPECT TO STRONG INELASTIC INTERACTION.** The cross sections of electrospallation of relativistic nuclei of varying atomic weight, which interact with uranium and a photoemulsion up to values of the Lorentz-factor of  $\gamma = 10^6-10^7$ , are calculated with consideration of screening. It is shown that the electrospallation reduces the mean free path with respect to strong inelastic interaction for the relativistic nuclei. (Author abstract) 4 refs.

Goryachev, B.I.; Lin'kova, N.V. *Sov Phys Lebedev Inst Rep* n 2 1987 p 32-36.

**078506 DYNAMIC MASS OF QUARKS IN A BAG MODEL.** The effect of the dynamic mass of quarks on the energy levels and wave functions of quarks is examined in a bag model. It is shown that corrections to these values caused by the dynamic mass do not exceed 1%, and cannot be experimentally detected with the current rate of precision. (Author abstract) 3 refs.

Solov'ev, A.A. *Sov Phys Lebedev Inst Rep* n 2 1987 p 54-56.

**078507 REINFORCING THE GRIBOV-SINGER THEOREM ABOUT GLOBAL CALIBRATION.** It is shown that in the non-Abelian field theory not only is there no global calibration, but even an incomplete global calibration, with which the residual group of symmetry is a finite Lie group, is impossible. (Author abstract) 10 refs.

Solov'ev, M.A. *Sov Phys Lebedev Inst Rep* n 2 1987 p 57-60.

**078508 GENERAL PROPERTIES OF THE POLARIZATION EFFECTS IN THE DECAYS.** The general structure is obtained of the polarization effects for the single-photon mechanism in the decays  $A \rightarrow B + l^+ + l^-$ . This structure takes into account possible violations of the P- and T-invariances in the electromagnetic interaction of hadrons. Use is made only of the principal properties of the electrodynamics of hadrons, such as the conservation of the hadronic electromagnetic current and the symmetry properties of the current under spatial and temporal reflections. (Author abstract) 13 refs.

**078519 COMPUTERS IN HIGH-ENERGY PHYSICS.** High-energy physics is a branch of science whose roots might be considered to go back to the pioneering experiment of Cockcroft and Walton in 1932 which, using

a beam of accelerated protons to split the lithium nucleus into two helium nuclei, demonstrated that the atomic nucleus was divisible. This field of research shares a common feature with computers - its dependence on progress in electronics to provide it with the capability to increase both the scale and the complexity of its performance. In this article we shall examine the use and impact of computers throughout the realm of high-energy physics research. It is the aim of this article not only to set out the way in which high energy physics has come to rely totally on computing, but also to point to those areas in which this field of research has itself been able to stimulate developments in computing. 60 refs.

**078525 DEVELOPMENT OF A SWITCHED CAPACITOR BASED MULTI-CHANNEL TRANSIENT WAVEFORM RECORDING INTEGRATED CIRCUIT.** A full-custom integrated circuit addressing the problem of transient analog signal recording is presented. The chip includes 2048 sample-and-hold cells, fast-clock-generation logic, and readout amplifiers. The sample-and-hold circuits are divided into 16 channels of 128 samples per channel. One read amplifier is used per channel. Clock signals are generated by on-chip redundant interleaved shift registers. The circuit is designed in an inexpensive and widely available 3- $\mu$ m, single-metal, double-polysilicon CMOS process that allows easy integration of high-density digital and analog circuitry with the possibility of very-low-power operation. Prototypes have been fabricated and proved to be operational. 7 refs.

**078526 ON THE IRREDUCIBILITY OF PROFESSOR G.F. SMITH'S REPRESENTATIONS FOR ISOTROPIC FUNCTIONS.** Irreducibility is proved of the basis for scalar-valued isotropic functions due to G.F. Smith, once the redundant elements found by J.P. Boehler are eliminated. Similarly Smith's basis for vector-valued, second order skew-symmetric tensor-valued and second order symmetric tensor-valued isotropic functions are proved irreducible. An argument by J.J. Telega leading to reducibility of the last of them is proved incorrect. (Author abstract) 26 refs.

Pennisi, S.; Trovato, M. *Int J Eng Sci* v 25 n 8 1987 p 1059-1065.

**078527 DIAGNOSIS OF DYNAMICAL SYSTEMS WITH FLUCTUATING PARAMETERS.** Many time evolutions occurring in nature may be considered as non-autonomous, but dependent on parameters that vary slowly with time. It is argued that some, but not all, of the tools used to understand chaotic dynamics remain useful in this situation. The asymptotic evolution takes place on a (usually) complicated set in phase space called a strange attractor. A fundamental finding is that hydrodynamic turbulence is chaotic, and described by strange attractors. (Edited author abstract) 7 refs.

**078528 UNIFIED APPROACH TO DENSITY FUNCTIONAL AND MOLECULAR DYNAMICS IN REAL SPACE.** The Lagrangian introduced previously by the authors is modified with the introduction of an auxiliary field that represents the Hartree potential. While

leading to the same results, the present version of the theory offers considerable practical and theoretical advantages. In particular, it provides the possibility of working entirely in real space, reducing the number of operations required. An interesting and potentially useful isomorphism of local density theory to a continuous spin lattice model is pointed out. (Edited author abstract) 6 refs.

Car, R. (Int Sch for Advanced Studies, Trieste, Italy); Parrinello, M. *Solid State Commun* v 62 n 6 May 1987 p 403-405.

**078529 DENSITY OF STATES OF ONE-DIMENSIONAL RANDOM POTENTIALS.** Following an introduction to the early history of the theories of the density of electronic states in one-dimensional structures, pioneered, among others, by R. Landauer and J.C. Helland, a particular model, that of a multistep random potential, is discussed. It is shown that Kolmogorov-type equations can be obtained for the probability distribution of the phase of the wave function, and, by solving these equations, the density of states may be calculated. An analogy with the classical rotator in a random force field is worked out, and helps in visualizing the results. (Author abstract) 9 refs.

Erdos, Paul. *IBM J Res Dev* v 32 n 1 Jan 1988 p 47-51.

**078530 CALCULATION OF THE POTENTIAL ENERGY OF THE INTERACTION OF AN ELECTRON WITH A MOLECULE.** We set forth a mathematically correct algorithm, simple in computer realization, for calculation of the potential energy of the interaction of an electron with a molecule and for the calculation of electric 2<sup>nd</sup>-pole molecular moments in the framework of the Hartree-Fock-Roothaan method. The proposed method permits consideration of the dynamics of the problem of the dependence of the energy on oscillatory motion in the molecule. (Author abstract) 11 refs.

El'kin, M.D. *Sov Phys J* v 30 n 8 Aug 1987 p 668-671.

**078531 INTRAMOLECULAR VOIDS AND INTERMOLECULAR CHANNELS.** Two algorithms are described for estimating the volume and surface area of intramolecular voids and intermolecular channels. One is a variant, the other a special case, of corresponding algorithms for filled spaces. In calculating hollows, the investigator has often to decree some of the bounds, that is, define a box that delimits the hollow. The choice of box and the positioning of species within the box are commented upon. (Author abstract) 19 refs.

**078534 LIFETIME MEASUREMENTS OF EX-**

**CITED QUANTUM STATES USING A DIODE LASER: RADIATIVE LIFETIME OF THE B<sup>2</sup>Σ<sup>+</sup> STATE IN BaCl.** A new method has been developed for measuring radiative lifetimes of excited molecular and atomic quantum levels. It is based on the unique time characteristics and the high spectral resolution of single mode diode lasers. The diode laser is tuned through the spectral region of interest at a high repetition frequency. With the delayed coincidence method fluorescence decay is recorded from each spectrally resolved line, allowing for lifetime determinations of several sequentially excited levels in each time-resolved spectrum. This method is applied on several rotational and vibrational levels of the B<sup>2</sup>Σ<sup>+</sup> state of gaseous BaCl. From the measured lifetime, 104±3 ns, band oscillator strengths and electronic transition moment were derived for the BaCl B-X transition. (Author abstract) 17 refs.

**078535 LIFETIME MEASUREMENT OF THE <sup>28</sup>Si COMPOUND STATE AT 13.095 MeV BY THE BLOCKING EFFECT.** The <110> axial and <111> planar blocking dips in an Al crystal are used to measure the lifetime of the state at 13.095 Mev in the compound nucleus <sup>28</sup>Si excited by the <sup>27</sup>Al(p, α)<sup>24</sup>Mg reaction at E<sub>p</sub> = 1565 kev. The blocking dips for 2.12 Mev α particles from this reaction at E<sub>p</sub> = 1183.4 kev are also measured and the radiation damage in the crystal is investigated. Monte Carlo simulations and analytical methods in the axial blocking measurement and analytical methods in the planar blocking case are used. The measured lifetime at the E<sub>p</sub> = 1565 kev resonance, τ = 15 ± 2 as, is in good agreement with the value derived from the reaction-yield measurement. (Author abstract) 18 refs.

**078538 MEASUREMENT OF FAST NEUTRON INDUCED FISSION CROSS SECTIONS OF AMERICIUM-243 RELATIVE TO URANIUM-235.** The fission cross section ratio of  $^{243}\text{Am}$  to  $^{235}\text{U}$  has been measured in the energy range of 1.1-6.8 MeV with monoenergetic neutrons. An ionization fission chamber was used to detect fission events. The quantitative analyses of the fission samples were made with a low geometry counter and a  $2\pi$  counter. Uncertainties of the measured data were analyzed considering correlations between error elements. The present result is very close to that of Fursov et al. and lower by about 20% than the values reported by Behrens & Browne. (Author abstract) 12 refs.

**078539 ISOMERIC RATIOS OF THE YIELDS (CROSS SECTIONS) OF PHOTONUCLEAR REACTIONS.** The relative probability of population of isomeric (metastable m and ground g) states of the final nucleus (isomeric ratio of yields  $d = Y^m/Y^g$  or cross sections  $r = \sigma^m/\sigma^g$ ) of photonuclear reactions (PNR)  $A(\gamma, x)^m \rightarrow B$  has been investigated intensively in numerous experimental works since the early 1960s. As yet, there has been no sufficiently complete review of experimental data on the IR of PNR yields. In the present work, values of the IR of PNR yields (cross sections) are given, together with a brief indication of the conditions in which they were calculated, either in the present work or elsewhere. 77 refs.

**078540 EMPIRICAL FORMULAS FOR 14-MeV (n,p) AND (n, $\alpha$ ) CROSS SECTIONS.** Empirical formulas for the 14 MeV (n,p) and (n, $\alpha$ ) cross sections given by Levkovskii were modified separately in three ranges of mass number, in each of which, coefficients modifying Levkovskii's formulas were determined by least-squares fitting to experimental cross sections. The resulting modified formulas yielded cross sections representing markedly smaller chi-square deviations from experimental values, and moreover gathered closer to unity, compared with calculation using Levkovskii's original formulas. (Author abstract) 8 refs.

**078541 ENERGY DEPENDENCE OF NUCLEON-NUCLEON INELASTIC TOTAL CROSS-SECTIONS.** The purpose of this article is to provide a phenomenological treatment of all existing nucleon-nucleon inelastic total cross-section data. More specifically, we have collected the data on exclusive and inclusive total cross-sections for reactions occurring in the NN system. We have then fitted the energy dependences of these

cross-sections by smooth curves with a reasonable number of free parameters, obtaining thereby a parametrization of the inelastic cross-sections for energies at which data are available. Whenever possible, we made comparisons between experimental total cross-sections and predictions following from isospin invariance. Finally the isospin decomposition (i.e. the  $I=0, 1$  cross-sections) for  $NN \rightarrow NN\pi$ ,  $NN \rightarrow d\pi$ ,  $NN \rightarrow NN\pi\pi$  and  $NN \rightarrow d\pi\pi$  processes is performed. 49 refs.

**078551 ACCURACY OF PROCESSED NUCLEAR DATA.** The results of the International Atomic Energy Agency cross-section processing code verification project are described. This project has been conducted over the last 7 yr in an attempt to improve the reliability of the results produced by cross-section processing computer codes. Initial comparisons of results received from 42 participants using 13 different cross-section processing codes demonstrated that, even though all of the codes started from exactly the same evaluated data, in no case did the multigroup cross sections calculated by any two codes agree for all materials and groups used in the comparison. This code verification project has led to positive results by improving cross-section processing codes as well as the conventions used to interpret ENDF/B evaluations. In several cases it has led to changes in ENDF/B evaluations. (Edited author abstract) 8 refs.

**078552 RECOIL DISTRIBUTIONS IN ISOTOPE SEPARATOR TARGETS.** The depth distribution of recoil daughter nuclei following the radioactive decay of implanted parent nuclei has been calculated. Moments of the depth distribution of the daughter nuclei are obtained

from tabulated moments of the usual range distributions of the parent and daughter atoms. The daughter nuclei are nearly symmetrically distributed about the mean implantation depth with a variance slightly greater than a third of the square of the mean range of the daughter. The distribution may be represented by a Pearson Type II distribution or by the form  $\exp(-a|x|)^p$ , with parameter  $p > 2$ . An example is given. (Author abstract) 4 refs.

**078553 VERIFICATION OF THE ACCURACY OF DOPPLER BROADENED, SELF-SHIELDED MULTIGROUP CROSS SECTIONS FOR FAST POWER REACTOR APPLICATIONS.** Over the last 5 yr the IAEA nuclear data processing code verification project has attempted to improve the accuracy of the results produced by processing codes. The first found of verification only considered unshielded, cold, group-averaged cross sections. In the second round of verification the effects of Doppler broadening and self-shielding are considered. In this paper we present verification results for Doppler broadening and self-shielding. One of the important results presented in this paper is that the original SIGMA1 method of numerical Doppler broadening as proposed by Cullen and Weisbin (1976) has now been demonstrated to be inaccurate and not capable of producing results to within required accuracies. Fortunately, due to this study, the SIGMA1 method has been significantly improved and the new SIGMA1 is now capable of producing results to within required accuracies. (Edited author abstract) 60 Refs.

**078554 INTEGRAL CATCHER ANALYSIS OF NUCLEAR RECOIL EXPERIMENTS.** The integral thick target thick catcher equations for extracting excitation and relaxation recoil velocities of nuclear reaction products have been reformulated. The new data analysis scheme corrects certain limitations and deficiencies inherent in the conventional procedure. Like the latter, our integral catcher analysis uses forward and backward recoil fractions F and B, but has no constraints on target thickness. The utility of the method may be extended with advantage to thinner targets. Additionally, there are no restrictions on the form of the range-velocity relationship that can be employed. Finally, the procedure inherently provides an excellent evaluation of the statistical uncertainties in the derived velocities based on the experimental uncertainties in F and B. (Author abstract) 20 Refs.

**078555 NUCLEON-NUCLEUS INTERACTION DATA BASE: TOTAL NUCLEAR AND ABSORPTION CROSS SECTIONS.** Neutron total cross sections are represented for Li to Pu targets at energies above 0.1 MeV and less than 100 MeV using a modified nuclear Ramsauer formalism. The formalism is derived for energies above 100 MeV by fitting theoretical cross sections. Neutron absorption cross sections are represented by analytic expressions of similar form, but shape resonance phenomena of the Ramsauer effect are not present. Elastic differential cross sections are given as a renormalized impulse approximation. These cross section data bases will be useful for nucleon transport applications. (Author abstract) 15 Refs.

**078556 APPLICATIONS OF THE SUBMICROSCOPIC NUCLEAR TRACK KINETIC THEORY.** The submicroscopic track kinetic theory (STKT) is able to

deal with a broad range of cases. We derive here its behavior for very short etching times (new born tracks) and also for long etching times, where the classical track kinetic theory is a particular case of the STKT. Experimental data obtained by previous researchers using the electroconductivity method are then analyzed by the STKT method. We show that good agreement is obtained between them and STKT theoretical results for the track diameter evolution. (Edited author abstract) 12 Refs.

**078559 CONTEMPORARY PROBLEMS OF THE PHYSICS OF THE STRENGTH OF SOLIDS.** A survey of the research carried out at the Institute of the Physics of Strength and Materials Science of the Siberian branch of the Academy of Sciences of the USSR into strongly excited states in crystals in application to the problem of the physics of plasticity and strength of solids is presented. Consideration of the theory of the behavior of solids in the fields of strong external effects leads to the concept of strongly excited states in crystals which is based on the appearance of permitted structural states in the interstitial space and the possibility of regular disposition of atoms not only in the crystal lattice modes but also in the interstices. A combination of this approach with the concept of structural levels of the deformation of solids and the principle of local calibration invariance makes it possible to substantiate the generation of a vortical mechanical field in a solid undergoing deforma-

tion. This theory is experimentally confirmed. Recommendations are given on the formation of vortical damping structures to create high-strength and wear-resistant materials. (Translated author abstract) In Russian. 33 refs.

**078562 QUANTUM DYNAMICS OF A DAMPED FREE PARTICLE.** We investigate the exact quantum dynamics of a free particle damped through its interaction with an harmonic bath, when the effective coupling strength behaves as  $\omega^6$  at low frequency. We find that various regimes can occur depending on the value of  $\delta$  and of the temperature. At large times, the mean square displacement is shown either to diverge as  $t^4$ , the exponent  $\nu$  being never greater than 2 or to tend towards a finite value, indicating a confinement in the broad sense. In addition, for  $\delta < 1$ , an oscillation (absent in the uncoupled system) is found: due to the friction on the dominant low-frequency modes and to the existence of retardation effects, the particle is forced to relax in the mean towards its initial location, the net dynamical effect of the bath being similar to that of an applied potential. In the limit  $\delta \rightarrow 0$ , the particle is frozen. (Author abstract) 13 refs.

**078564 MODIFIED OPTICAL POSITRON MODEL. POSITRON ANNIHILATION IN IONIC MEDIA.** Positron annihilation from a positron-anion bound state is considered. A critical analysis of the optical positron model is given, and a modification is suggested with the purpose of removing drawbacks of this model. A calculation of angular correlation curves and positron life time is carried out. In the calculation we explicitly account for repulsion forces between the positron and the nucleus, dominating at short distances. It is shown that the inner electron of the anion plays no significant role in the formation of the angular correlation curve, and does not affect the value of the positron lifetime. The model makes

it possible to determine the effective anion charges and the value of the repulsion force between the positron and the nucleus from experimental angular correlation curve and positron lifetimes in ionic media. Specific analysis is carried out for the  $O_2^-$  ion. (Author abstract) 7 refs.

**078572 CONTRIBUTIONS TO THE SECOND ORDER DIELECTRIC RESPONSE OF AN ELECTRON LIQUID.** The dielectric response function  $\chi$  of a uniform electron gas is investigated up to the second order of the Coulomb interaction with different methods. When examining all polarization diagrams with two interaction lines, it is confirmed that previous work in the Green's function formalism does not contain all second order processes and the importance of the corrections is pointed out. It is further shown how the evaluation of  $\chi$  with Green's function can be greatly simplified when taking into account the symmetry of the expressions. (Author abstract) 19 refs.

**PICKLING** See Also FASTENERS—Protective Coatings; ROLLING MILLS—France.

## Electrodes

**078576 GETTING THE LEAD OUT.** Lead is very effective as an anode but it dissolves into the bath. Carbon would be effective, too, but it also dissolves and has a short life. State Plating had been considering platinized titanium, but that was expensive. In electrolyte pickling prior to plating, specially coated titanium is the replacement. The new anodes help to lessen water pollution and lower cost at the same time.

**Energy Conservation** See STEEL—Pickling.

## Waste Disposal

**078577 RECOVERY OF FERROUS SULFATE AND SULFURIC ACID FROM SPENT PICKLE LIQUOR OF THE STEEL INDUSTRY.** This paper demonstrates that spent sulfuric acid pickle liquor can be recycled by recovering sulfuric acid and ferrous sulfate. This is achieved by removing part of the water from the liquor followed by ferrous sulfate crystallization and separation of the ferrous sulfate from the resulting slurry. Depending on energy consumption, three cases of carrying out the process can be distinguished. The percentage of sulfuric acid recovered for these three cases was 92.4, 90.4 and 89.7, respectively, and the percentages of ferrous sulfate recovered were 69.7, 85.3 and 92.7, respectively. The sulfuric acid concentration in the respective filtrates increased from 7.62% in the spent pickle liquor to 17.7%, 19.5% and 35.5%. The ferrous sulfate concentration decreased from 15.1% to 11.5%, 6.31% and 5.75%, respectively. The crystals of recovered ferrous sulfate contained small amounts of occluded sulfuric acid. (Author abstract) 6 refs.

## Waste Utilization

**078578 AQUATECH SYSTEM - A COMMERCIAL PROCESS TO RECYCLE SPENT PICKLE LIQUOR.** AQUATECH Systems has developed an electrochemical membrane process that economically separates salt solutions into their constituent acids and bases. The technology transforms the once-through pickling process into an essentially closed-loop operation with minimal chemical makeup requirements and potentially no disposal costs. It has been piloted at the Washington Steel facility in Washington, Pa., for over two years, resulting in the design and construction of the first commercial plant. The plant will regenerate over 1.5 million gal of spent pickle acid per year into reusable  $HF/HNO_3$  acid as well as eliminating disposal costs now estimated at \$0.55/gal (\$860,000 annually). 1 ref.

## PICKUPS

**078579 OPTICAL TECHNOLOGY FOR COMPACT DISK PICKUPS.** Instead of a stylus, the compact audio disk player employs an optical pickup head to reproduce high-quality sound over a wide dynamic range from prerecorded disks. The laser beam from the optical pickup illuminates a very small area of the recording surface, so that information recorded on the disk can be sensed by a detector. The detectors also provide signals to a servo system to control the movement of the objective lens so that the laser beam is kept focused correctly on the track. Therefore, the optical pickup is the most important device in the compact disk player; it links the recording medium with the electronic and mechanical systems. In this article we shall review only the optical pickup technologies for the compact disk player. A new technol-

ogy for using holographic optical elements will improve the cost/performance ratio of the optical pickup head. 1 ref.

Lee, Wai-Hon (Pentcom Int Corp, Santa Clara, CA, USA). *Lasers Optonics* v 6 n 9 Sep 1987 p 85-87.

**Applications** See SURFACES—Roughness Measurement.

## Performance

**078580 DEVELOPMENT OF THE FOCUSING AND THE TRACKING ACTUATOR IN AN OPTICAL DISC SYSTEM.** Optical pickups are used to pick up information from optical discs and are important for optical disc systems such as compact-disc (CD) players. To pick up information from discs without physical contact, an optical pickup is provided with an actuator which drives a laser spot on the disc surface according to the disc deflection and the track deviation. The driving efficiency is an important factor regarding actuators. Through development of forming and magnetization technics and elaborate analysis of the magnetic field, it was possible to significantly improve the driving efficiency. 7 Refs.

## PIERS

### Concrete Construction

**078581 COMMERCIAL BOAT PIER C-1.** The article discusses how precast prestressed deck channel sections, finger pier slabs, piles and pile caps provide strength, durability and economy for a 416 ft (127 m) long commercial boat pier situated in a hurricane prone harbor. This precast prestressed concrete commercial boat pier, with 51 boat slips, was built for docking 40 to 55 ft (12.2 to 16.8 m) long fishing boats. It is located in a picturesque part of Pass Christian Harbor, Pass Christian, Mississippi. (Edited author abstract)

Anon. *PCI J* v 33 n 1 Jan-Feb 1988 p 142-147.

### Failure

**078582 EFFECT OF CREEP ON THE UPLIFT BEHAVIOUR OF DRILLED PIERS.** A pier in tension under the action of a design load may collapse not because the static collapse load had been wrongly estimated but because the creep on the shaft-soil interface due to the sustained load had influenced the pullout behavior of the foundation. Laboratory model tests were carried out on short concrete piers in a compacted soil. Some piers were subjected to uplift forces to determine the ultimate failure load while others were subjected to various design loads. They were subsequently pulled out to failure. Results showed that the pullout behavior of piers is influenced by the occurrence of creep on the pier-soil interface and that the post-creep pullout capacities are dependent on the design (creep) loads sustained on the pier. (Author abstract) 13 refs.

Akinmusuru, Joe O. (Univ of Ife, Ife-Ife, Nigeria). *Int J Struct* v 7 n 2 Jul-Dec 1987 p 199-208.

### Foundations

**078583 REINFORCEMENT EFFECTS OF PIER FOUNDATION BY QUICK-LIME CONSOLIDATED BRIQUETTE PILE.** The bearing storage of foundation pile has turned out in earthquake by the examinations of several kinds of pile of pier constructed in the decade from 1955. Quick-lime consolidated briquette pile method used as a protection method against the weak point of pier foundation is described from the following viewpoints: investigation results of piled foundation, discussion of the protection methods, planning and construction of the protection methods, and confirmation of improvement

effects. (Edited author abstract) 5 refs. In Japanese.

Ito, Takao; Asada, Akie; Konno, Tatsuo. *Tohoku Kogyo Daigaku Kiyo* 1 n 8 Mar 1988 p 59-72.

### Repair

**078584 REHABILITATION OF SOUTH PIER, GODERICH HARBOUR.** This article deals with the deepening of an existing pier to allow berthing of fully loaded vessels operating in the North American Great Lakes and inland waterway system. The existing pier is a complex structure. The article discusses a method used to investigate the strength of the structure, the difficulties encountered and the limits to which improvements could be achieved. The article presents the solution finally devised and describes the method used in its analysis. The article also deals with the construction of the rehabilitation work, problems during the construction and solutions. (Author abstract).

Shah, V.K. (Public Works Canada, Can). *Bull Perm Int Assoc Navig Congr* v 61 1988 p 34-45.

### Structural Analysis

**078585 DYNAMIC CHARACTERISTICS OF PIERS SUBJECT TO BERTHING FORCES.** The effects on the berthing force due to: the masses of pier and ship; the stiffness of pier and fendering system; and the velocity of the ship berthing have all been investigated. A simplified mathematical model has also been developed to predict the berthing force. Three different mathematical models have been used to represent the pier deck and are employed in the dynamic analysis to obtain the dynamic behavior of piers subjected to ship berthing. The parametric study shows the influence of the rigidities of the pier deck on the dynamic behavior of the pier. A suggestion for the practical dynamic design of pier has been given. Field observation of piers subjected to ship berthing and ambient vibrations has been carried out, and results are discussed. (Edited author abstract) 10 refs.

### Vibrations

**078586 PRELIMINARY ANALYSIS OF THE DAMPING COMPOUND VIBRATION OF DEEP-WATER PILE PIER DUE TO IMPACT OF AN APPROACHING SHIP.** A method is proposed for the analysis of the compound vibration of a deep water pile pier equipped with a rubber fender system. The analysis is based on an hypothesis. During the plastic impact between the ship and the pier through the rubber fender, the motion behavior of the system is assumed to be free vibrations with damping and five degrees of freedom in a horizontal plane. The general solutions of the damped compound vibration are derived. With an illustrative example, the influence of the main parameters on the impact force, compression of the rubber fender, dynamic resistance and displacement of the piles is analyzed. (Edited author abstract) In Chinese. 6 refs.

**078587 COIL-LESS MINIATURE PIEZOELECTRIC CERAMIC TRANSFORMER.** A coil-less miniature piezoelectric transformer has been designed and fabricated using NPLZT-5 ceramic material. Such transformers are superior to other transformers in that these are light weight, small in size and coil-less thus eliminating electromagnetic interference. A voltage gain up to 10 can be obtained with the transformer developed. Linearity in gain has been observed from the input-output voltage characteristics curve at the input voltage studied. The effect of acoustic damping due to the medium in which the transformer vibrates has also been studied. Results ob-

tained in vacuum, air and oil have been discussed. The effect of temperature and position of mounting on voltage gain has also been studied. (Author abstract) 13 refs.

**078588 MICROPOSITIONING USING PIEZOELECTRIC TRANSLATORS.** The phenomenon of piezoelectricity was discovered by the brothers Pierre and Jacques Curie in 1880. It was merely a scientific curiosity until Langevin began to use it in ultrasonic transducers at the start of World War I, which marked the beginning of a series of rapid developments. The piezoelectric effect is now used in an enormous variety of applications relating to the conversion of electrical energy to mechanical energy. This article introduces piezoelectricity and discusses some of its recent applications. The article shows how piezoelectric translators offer fine movement with speed and force for new levels of precision. 10 refs.

**078589 USE OF PIEZOELECTRIC VIBRATION GENERATOR FOR VIBRATORY ASSEMBLY OF A RING ON A SHAFT WITH AN INTERFERENCE FIT.** Modern manufacturing engineering, especially precision instrument manufacturing, calls for tightened specifications for assembly of shaft-bush subunits with interference (for example, press-fitting of a precision ball bearing on the shaft). The most rational solution of the problem can be achieved by means of a vibration stimulation of the part being pressed on. Resulting elastic vibrations in the part are decreasing the effective pressing force (P). A model is shown of the assembly device, employing a ring-shaped piezoceramic vibration generator (PVG). The authors consider the mathematical model of a device permitting one to calculate the optimum parameters of the PVG. 1 ref.

### Pumps

**078591 PIEZOELECTRIC MICROPUMP BASED ON MICROMACHINING OF SILICON.** The design and realization of two pumps based on micromachining of silicon are described. The pumps, which are of the

reciprocating displacement type, comprise one or two pump chambers, a thin glass pump membrane actuated by a piezoelectric disk and passive silicon check valves to direct the flow. Chambers, channels and valves are realized in a silicon wafer by wet chemical etching. The results of mechanical calculations and simulations show agreement with the actual behavior. It is possible to design pumps having a specific yield and pressure dependence, and which are fail-safe (the flow is blocked while the pump is switched off). (Edited author abstract). 9 Refs.

**078592 NONSTATIONARY VIBRATIONS OF A SECTIONED PIEZOELECTRIC CYLINDER IN ELECTRIC FIELD.** Until now there have been published relatively many papers devoted to studying periodical in time processes in piezoelectric bodies. Under the influence of electric impulses of short duration or shock loads the conditions of work of construction elements made of piezoelectric materials can be substantially nonstationary. The rules of behavior of electroelastic transducers under nonstationary electrical or mechanical perturbation are practically not studied at all. This article presents a method of solution of nonstationary wave problems of electroelasticity which is illustrated on the example of perturbation of a circular thick-walled piezoelectric cylinder by a nonstationary electric signal. It is assumed that the cylinder is of infinite extent and is polarized along the angular coordinate (circular polarization). 11 refs.

**078593 VIBRATION FIELD CALCULATION FOR PIEZOELECTRIC VIBRATION GENERATORS OF WAVE-TYPE VIBROMOTORS.** In wave-type vibromotors (VM), various types of piezoelectric generators are used as input (driving) members for two and three dimensional wave vibrations generation. Interaction of the input and output members in VM can be investigated by solving the set of not less than four partial differential equations of the fourth-sixth order. It is quite complicated, even with computers. A computational method for steady vibration field parameters when the input member interacts with the output member, is presented in this paper. 5 refs.

Kurilo, R.; Ragulskis, K. *Vib Eng* v 1 n 1-4 1987 p 183-191.

**078594 TORSIONAL VIBRATION OF A PIEZOELECTRIC SOLID CYLINDER OF ARBITRARY CROSS SECTION OF (622) CLASS.** The torsional vibration of a piezoelectric solid cylinder of arbitrary cross section of class (622) crystals is investigated. The boundary conditions are satisfied using the Fourier expansion collocation method, and the frequency equation which is applicable for the general cross section is derived. Numerical calculations have been carried out for the circular cylinder and elliptic cylinders of  $\beta$ -quartz. The frequencies obtained in the present method for the circular cylinder are compared with those of an exact method. (Author abstract) 28 refs.

**078595 NEW PIEZOELECTRIC POLYMERS.** Piezoelectricity and pyroelectricity, traditionally encountered in single crystals and ceramics, have now been documented in a number of polymers. The most successful and widely used polymer is polyvinylidene fluoride (PVF<sub>2</sub>) which has been shown to be ferroelectric. The copolymers of PVF<sub>2</sub> with related fluorinated vinyl monomers also exhibit piezoelectric activity and those with trifluoroethylene (VF<sub>2</sub>) show enhanced activity over the homopolymer. These particular copolymers crystallize into an intrinsically piezoelectric crystal phase from the melt and thus offer advantages in processing and potential application. This paper compares piezoelectric consumers obtained for commercially available PVF<sub>2</sub> with those for a series of PVF<sub>2</sub>/VF<sub>2</sub> copolymers. One copolymer shows a 50 percent increase in activity over PVF<sub>2</sub> when evaluated as a hydrophone material. The chemistry of alternative piezoelectric polymers is described. Areas of application are presented. (Edited author abstract) 27 refs.

Suttle, N.A. *GEC J Res* v 5 n 3 1987 p 141-147.

**078596 AXISYMMETRIC CONTACT PROBLEM OF ELECTROELASTICITY FOR A HALF-SPACE.** In a series of devices for electromechanical energy transformation one makes use of combined metal-ceramics (metal-piezoelectric ceramics) structures and one applies elements with separated electrodes of various configurations. The investigation of the contact rigidity of such elements under various supply and removal of electric energy regimes is of both scientific and practical interest. In this paper one obtains the exact solution of two contact problems regarding the pressing of a circular rigid punch against a piezoelectric ceramics half-space ( $z \geq 0$ ) with axial polarization. In the first case the boundary of the half-space is without electrodes, while in the second case one has a circular electrode whose radius is equal to the radius of the punch. On the basis of the obtained results it is concluded, that in calculating contact interactions in metal-ceramics structures, it is necessary to take into account the electric operating regimes of the piezoelectric ceramics elements. 6 refs.

**078597 POTENTIALITIES OF THE AVERAGING METHOD IN THE PROBLEM OF WAVE PROPAGATION IN AN ELECTROELASTIC LAYER WITH PERIODIC NONUNIFORMITY OVER THE THICKNESS.** An earlier paper developed analytic and numerical methods for investigating wave processes in a layer made up of a number of piezoceramic layers. For structures with large numbers of layers, however, the numerical methods involved entail large amounts of machine time. This stems from the fact that the coefficients in the differential equations of motion are highly variable over the thickness, and thus an excessively small integration step must be chosen. In this paper, for the case of a periodic thickness nonuniformity, we employ the averaging method to set up equations whose coefficients are not rapidly variable, and whose solutions are close to the solutions of the original problem. We offer a detailed investigation of the changes in the dispersion set that arise as a result of averaging, and we estimate the error of the proposed method. (Edited author abstract) 4 refs.

**078598 COLLISION OF PIEZOCERAMIC RODS.** We consider identical piezoceramic rods that are initially polarized along their axes. There are electrically grounded electrodes on the end faces of the rods. An electrode is

inserted at the center of the first rod and is joined rigidly to it. It is assumed that a second rod moves with velocity  $v_0$  in the positive direction of the x axis toward the first rod, which lies on the same x axis on the interval  $0 < x < Z$ . These two rods collide at time  $t=0$ . We determine the electroelastic stressed state of the rods for  $t > 0$ , and the duration of the impact. Our results enable us to propose a technique for experimentally measuring the moduli of electroelasticity of piezoceramics (for small  $k_2$ ). 4 refs.

Chau, Le Hanh. *Mech Solids* v 22 n 3 1987 p 178-181.

**078599 MINI MOTION-DETECTOR SENSES IR WITH PIEZO FILM 'RETINA'.** This method of operation is based on the 'pyroelectric' energy conversion properties of a plastic piezoelectric film. Selectively sensitized, a semicylindrical strip of this infrared-sensitive material provides a retina-like function. Incident infrared (IR) radiation is focused on the 'retina' by a wide-angle plastic lens. Whenever IR energy from a moving heat source passes across its surface, the retina's pyroelectric properties generate a transient voltage. The voltage signal is amplified and analyzed by logic circuitry. This circuitry can be designed to recognize the entry or departure of a warm object of a specific size. It only reacts to objects passing through the area visible to the lens.

**Crystal Lattices**

**078602 CRYSTALLOGRAPHIC ASPECTS OF UNIT CELL DISTORTION IN Pb(Zr, Ti)O<sub>3</sub>-Pb(Co, Nb)O<sub>3</sub> SOLID SOLUTIONS.** Pb(Co, Nb)O<sub>3</sub> (PCN) has a perovskite structure and a very low Curie temperature of  $-70^\circ\text{C}$ . Since the lattice parameters of PCN are very near those of Pb(Zr, Ti)O<sub>3</sub> (PZT), PCN and PZT readily form a solid solution. In the present work, the crystallographic phases and dielectric properties of PCN-PZT

solid-solution ceramics were investigated with respect to the degree of solid solution. For each sintering temperature, the lattice parameters as a function of the substituted PCN concentration are given. For all temperatures the lattice parameter along the axis is markedly decreased with an increase in PCN concentration; however, the lattice parameter along the a axis is slightly increased. Therefore the symmetry of the unit cell should be decreased as the degree of substitution of PCN is increased. Plots of the relative dielectric constant and planar electromechanical quality factor of the ceramics prepared at 1120°C against the concentration of PCN are also given. 11 Refs.

## Electromagnetic Field Effects

**078605 CHARACTERISTIC MODES OF OSCILLATION IN A PIEZOELECTRIC SEMICONDUCTOR IN AN ALTERNATING ELECTRIC FIELD.** The characteristic excitations in a piezoelectric semiconductor in an alternating electric field are studied theoretically. The coupled equation for the strain, charge density, electric fields, and the current in the piezoelectric semiconductor are solved using the continuous-fraction formalism. Analytic expressions are presented for the characteristic modes of the system and its Green's function. (Author abstract) 12 refs.

Gulyayev, Yu.V.; Kozorezov, A.G.; Mansfel'd, G.D. *Sov J Commun Technol Electron* v 32 n 8 Aug 1987 p 142-151.

**Energy Dissipation** See CERAMIC MATERIALS—Piezoelectric.

## Evaluation

**078606 CHARACTERIZATION OF PIEZOPLASTICS.** An evaluation method for piezoelectric plastics is presented. The method allows the intrinsic characteristics in the thickness mode to be obtained. It is based on the fitting of simulated and measured electrical impedance-frequency curves. The simulated curves are derived from a Mason model that takes into account the mechanical and dielectric losses of the material and their possible frequency dependences. Finally, an extension of the

method is described for the characterization of non-piezoelectric materials. (Author abstract) 11 refs.

## Fiber Reinforcement

**078607 EFFECTIVE CONSTANTS OF PIEZOACTIVE COMPOSITES OF STOCHASTIC STRUCTURE.** Interest has recently increased in developing new piezoelectric materials, possessing enhanced stability properties. One of the promising directions in solving this problem is the creation of composite materials on the basis of piezoelectric (piezoelectric and piezomagnetic) ceramics, reinforced along the polarization axes by high-modulus anisotropic monocrystalline or polycrystalline fibers. A method is suggested in the present study for calculating the effective constants of piezoactive composites of a stochastic structure, based on applying the apparatus of conditional moment functions. The method can be used for prognosis of electroelastic and magnetoelastic characteristics of strongly inhomogeneous composites with arbitrary component concentrations. (Author abstract) 10 refs.

**078608 EXTERNAL ULTRASOUND CAN GENERATE MICROAMPERE DIRECT CURRENTS IN VIVO FROM IMPLANTED PIEZOELECTRIC MATERIALS.** Under development is an internal fixation plate that incorporates a piezoelectric element to generate current when excited mechanically by either weight bearing or external application of ultrasound. The intent is to deliver this current to electrodes at a fracture or osteotomy site to aid in prevention or treatment of nonunion. The present study examines quantitatively the ability of external ultrasound to generate current from small piezoelectric ceramic elements implanted in tissue. An ultrasonic transducer was employed to excite small test coupons of a piezoelectric ceramic in vitro and in vivo with various materials, including water, PVC gel, cortical bone, and living soft tissues, interposed. (Edited author abstract) 7 refs.

## Morphology

**078609 MORPHOLOGY OF LEAD ZIRCONATE-TITANATE SINTERING PRECURSORS.** Studies on sintering are performed in order to find out the relationship between powder morphology, green density, chemical composition, inhomogeneities, heating program, atmosphere on the one hand and shrinkage, microstructure and physical properties on the other hand. In this situation the properties of the initial raw materials are very important. Thus, the powder morphology determined by the kind of precursor and its decomposition type is a decisive factor for the sintering result. In this paper, additional evidence is presented relative to the complexity of the lead zirconate-titanate ceramic problem, when the powder characteristics are highly dependent on the kind of precursors, the solid state reaction during sintering

being complex. 5 refs.

**078610 TEMPERATURE VARIATION OF THE DEBYE-WALLER FACTOR OF  $\text{NaNO}_2$ .** Sodium nitrite shows piezoelectric property at room temperature and has a phase transition in the range 160 to 166°C. In the present work measurements were carried out with the object of extracting the overall X-ray Debye-Waller factor (B) for  $\text{NaNO}_2$ . The motivation was to study the variation of overall Debye-Waller factor (B) of  $\text{NaNO}_2$  with temperature below and above the phase transition. The Debye-Waller factor decreases with increases with temperature below the phase transition, and increases with temperature above the phase transition. 10 Refs.

## Plastics Applications

**078611 WIDE-BAND PIEZOELECTRIC POLYMER ACOUSTIC SOURCES.** The design of a wideband acoustic source made of the piezoelectric polymer polyvinylidene fluoride (PVDF) is described. The source was developed for the characterization and absolute calibration of ultrasonic hydrophone probes. Construction details are described and performance characteristics of the wideband PVDF transmitter, including its transmitting voltage response and directivity patterns, are compared with theoretical predictions in the frequency range up to 40 MHz. The Krimholtz-Leedom-Mattaei (KLM) model was used to examine the influence of the PVDF polymer film thickness, the backing acoustic impedance, the cable length, and the electrical source resistance on overall transmit transfer characteristics. A comparison is made with traditional piezoelectric ceramic acoustic sources, and it is shown that piezopolymer transmitters exhibit some improved properties and are well suited for certain ultrasound dosimetry applications. In particular, the polymer sources have been found useful in measurements based on swept-frequency excitation. Those measurements allow characterization of transmitters and receivers to be performed as a virtually continuous function of frequency. 35 refs.

**078612 TRANSPARENT  $(\text{Pb}, \text{Ca})(\text{Zr}, \text{Ti})\text{O}_3$  CERAMIC OBTAINED WITH THE AID OF THE ALKOXY TECHNOLOGY.** An ecologically clean method of synthesizing the complex oxides  $(\text{Pb}, \text{La})(\text{Zr}, \text{Ti})\text{O}_3$  (lead lanthanum zirconate titanate) is the so-called alkoxy technology—namely, the hydrolysis of metal alcoholate solutions in an organic solvent medium with subsequent heat treatment of the complex-oxide hydrate formed. A study was made of the process of formation of a lead lanthanum zirconate titanate solid solution of composition  $\text{Pb}_{0.90}\text{La}_{0.10}(\text{Zr}_{0.65}\text{Ti}_{0.35})_{0.975}\text{O}_3$  from an amorphous precipitate forming during the hydrolysis of an alcohol solution of titanium and zirconium alcoholates by an aqueous solution of Pb and La acetates or only  $\text{La}(\text{CH}_3\text{COO})_3$  in the presence of solid  $\text{PbO}$ . After annealing at 600°C for 30 minutes a single-phase crystalline product with an average crystallite size of about 150 Å is formed.

**078613 EFFECT OF THE PRECIPITATION TEMPERATURE ON THE STRUCTURE AND PROPERTIES OF A BISMUTH AND TITANIUM COPRECIPITATE.** A study was made of the effect of the precipitation temperature on the dispersion characteristics, phase composition and chemical activity of a bismuth and titanium coprecipitate. With an increase in the precipitation temperature an increase in primary precipitation particles and secondary agglomerates is observed. These processes are accompanied by loss of the phase homogeneity and a decrease in the chemical activity of the precipitate, which causes an increase in the bismuth titanate synthesis temperature. From these samples a ceramic was sintered. Studies showed that at a given sintering temperature the density of the ceramic is lower in powders obtained at high temperatures. For the preparation of a ceramic with a maximum density from these powders high sintering temperatures are required. (Translated author abstract) In Russian. 6 refs.

## Thermal Expansion

**078615 THERMAL DEFORMATIONS AND PHASE TRANSFORMATIONS IN TOURMALINES.** In air, Tourmalines are stable up to 825-995°C, depending on their composition. The decomposition products are mullite and an X-ray amorphous phase, and also hypersthene in the case of magnesium-containing varieties and spodumene in the case of lithium-containing varieties. Up to 400°C, only a thermal expansion which is more intense along the c-axis occurs. In iron-containing tourmalines above 400°C oxidation of iron begins. The result is compression of the structure along the a-axis with compensation of the thermal expansion and a sharp increase in the c-parameter at high temperatures. The directions of the maximum thermal expansion, the maximum amplitudes of the thermal vibrations of atoms, and the minimum refractive index in the Tourmaline structure coincide with each other and are perpendicular to packets of the (001) structure. In Russian. 12 refs.

**078616 STRUCTURAL CHARACTERISTICS OF ZINC OXIDE FILMS.** A study was made of the structural characteristics of ZnO films deposited by three-electrode sputtering, using the methods of X-ray diffractometry and vibrational spectroscopy. It is shown that the investigated ZnO films possess residual elastic

stresses. By enriching the sputtering atmosphere with oxygen, ZnO films without residual elastic stresses (equilibrium films) can be obtained. In spite of the fact that, by combining sputtering with heat treatment, it is possible to obtain fine-crystalline ZnO films without mechanical stresses, in the surface layer of the substrates irreversible changes resulting from the action of the initially deformed film in the substrates may remain. In Russian. 10 refs.

## Vibrations

**078617 DETERMINATION PAR LA METHODE DES ELEMENTS FINIS DES MODES DE VIBRATION DES CERAMIQUES PIEZOELECTRIQUES.** [Determination of the Modes of Vibration of Piezoelectric Ceramics by the Method of Finite Elements]. The solution of the general expressions for the propagation of vibrations in piezoelectric materials is only possible using certain simplifying assumptions. In contrast the numerical methods of solving partial differential equations are perfectly adapted to this type of problem. They are an effective and indispensable tool for determining the stress fields and deformations of vibrating elements to be used for the manufacture of transducers for imaging or echography. Since existing finite element codes do not take account of the piezoelectric effect, we have written our own finite element program, but limiting it to the case of materials with simple geometries. We describe the general structure of our algorithm and then present the results obtained from the simulation. (Author abstract) In French. 37 refs.

## Analysis

**078620 EQUIVALENT CIRCUIT ANALYSIS FOR TONPILZ PIEZOELECTRIC TRANSDUCER.** Tonpilz piezoelectric transducers are one style of transducers for high-power sound generation. However, the transducers have mainly been designed by the trial-and-error method. This paper precisely estimates the transducer performances beforehand by an equivalent circuit analysis. The precise electro-mechano-acoustical equivalent circuit is derived for the transducer, including housing, an acoustic rubber layer and a bolt, and its transmission matrix is presented. To improve the calculation accuracy, the effects of adhesive layers in a piezoelectric ceramic stack part and compressive stress by bolting them

together are included into the electrical and mechanical equivalent constants for the ceramic stack. To accurately evaluate any errors between theoretical and measured values, transducer performances are expressed as absolute values in MKS units. Based on this analysis, a Tonpilz transducer has been built. Transmitting and receiving voltage sensitivities for the transducer, as well as the respective resonant frequencies, mechanical quality factors and free admittance loci in air and in water, have been measured. ## Design

**078621 FREQUENCY CHARACTERISTICS OF THE SENSITIVITY OF A TWO-LAYER PIEZORECEIVER WITH OPPOSITE POLARIZATION OF LAYERS.** On the basis of calculations it is shown that if sections are connected in series with opposite polarization, the piezoreceiver has wide-range properties. The working range was expanded to a certain extent using a two-layer transducer with opposite polarization of the layers. A planar sound wave travels to the transducer from one side, e.g., from a liquid. On the other side, the transducer borders with air or is covered with an acoustically soft screen. The sections of the transducers are connected in series. The resultant electrical voltage at the output of the transducer is equal to the difference of the voltages which would form in each of the layers if the polarization direct were the same. **078623 MONOLITHIC BIMORPH WITH INTERNAL ELECTRODES.** Monolithic bimorphs with internal electrodes which are composed of two, three and four layers were made from the high  $d_{31}$  material of a modified  $\text{Pb}(\text{Ti}, \text{Zr})\text{O}_3$ . The new bimorphs utilized unstiffened mode and were used as large-displacement transducers under low DC bias. Those bimorphs with four layers generate displacement of up to 0.6 mm at a voltage of 30 V with 4 msec response. The force induced by the DC bias was in proportion to the bias. Hysteresis of the displacement became smaller by introducing an intermediate layer or internal Pd electrodes. (Author abstract) 6 refs.

## Medical Applications

**078631 APPLICATION OF PIEZO/PYROELECTRIC FILMS IN MEDICAL TRANSDUCERS.** Piezo-/pyroelectric films are capable of generating electrical signals in response to mechanical stress or heat flow, making them the equivalent of a capacitor connected in parallel with a leakage resistor and current source. The piezo- and pyroelectric coefficients, and electrical and thermal time constants of such films can be useful in the design of medical sensors. The author describes three electronic interface circuits: a voltage follower, current-to-voltage converter, and charge-to-voltage converter. Applications for such transducers include a contact microphone, strain-gauge plethysmograph, respiration monitor, thermal imaging sensor, 'instant' thermometer, and a thermal scanner. (Author abstract) 7 refs.

**Performance** See Also LASER BEAMS—Measurements; PRESSURE TRANSDUCERS—Performance.

**078633 CHARACTERIZATION OF NONCONTACT PIEZOELECTRIC TRANSDUCER WITH CONICALLY SHAPED PIEZOELEMENT.** The characterization of a dynamic surface displacement transducer (IQI Model 501) by a non-contact method is presented. The transducer is designed for ultrasonic as well as acoustic emission measurements and, according to the manufacturer, its characteristic features include: a flat frequency response range which is from 50kHz to 1000kHz and a quality factor Q of less than unity. The characterization is based on the behavior of the transducer

as a receiver and involves exciting the transducer directly by transient pulse input stress signals of quasi-electrostatic origin and observing its response in a digital storage oscilloscope. Theoretical models for studying the response of the transducer to pulse input stress signals and for generating pulse stress signals are presented. The characteristic features of the transducer which include the central frequency  $f_0$ , quality factor Q, and flat frequency response range are obtained. They compare favorably with those obtained by a tone burst method which are also presented. (Edited author abstract). 30 Refs.

**078637 ALLOWING FOR THE INDIVIDUAL FEATURES OF TRANSDUCERS WHEN PLOTTING ARD-DIAGRAMS.** Various piezoelectric transducers (PET) are produced, some of which can be used only for UT of an actual finished item. The differences in PET characteristics are due to the properties of the materials, the designs, the manufacturing techniques and so forth. The use of dimensionless ARD-diagrams with these PET give rise to additional errors in determining  $S_0$  because of the differences in transducer operating conditions, which becomes particularly apparent in the short-range zone of PET. This article outlines the results of an investigation into the possibility of describing the short-range and long-range zones of a transducer by a single approximating function.

**078638 CONTRIBUTION OF MACROSCOPIC DIMENSION EFFECT TO PIEZOELECTRICITY IN POLYVINYLIDENE FLUORIDE.** In this paper, we have studied the piezoelectricity in the poled uniaxially drawn polyvinylidene fluoride. The piezoelectric constants  $d_{31}$ ,  $d_{32}$ ,  $d_{33}^*$  and Young's moduli  $1/s_{11}$  and  $1/s_{22}$  have been determined as a function of the remanent polarization  $P_r$ . The piezoelectric constants of the samples show a strong in-plane anisotropy. Such an anisotropy is mostly attributable to different Poisson's ratio. It is found that the piezoelectric activity mainly arises from macroscopic dimensional change. (Author abstract) 22 refs.

**078642 POSSIBILITIES OF REDUCING THE MANGANESE AND SILICON CONTENT OF PIG IRON IN RELATION TO SULPHUR CONTENT**

**AND CARBON OXIDATION KINETICS.** In Czechoslovak steelplants, pig iron is produced from iron ore containing mostly 0.05-0.56% Mn. Therefore, Mn ore with 36-45% Mn is added to the blast furnace charge. In addition to Mn ore, recirculating steelmaking slag with 4.44-5.6% Mn and also 0.49-1.5% P is added. In the conditions existing in Czechoslovak steelworks, a reduction of 0.1% in the manganese content of pig iron is expected to save 5.5 kg of manganese ore, 1.5 kg/t of coke, and improve output by 0.3%. The Mn, Si and S content has a negative effect on the kinetics of carbon oxidation. 7 refs.

**Production**

**078643 ENTWICKLUNG DER ROHEISEN-PRODUKTION IN VANDERBYLPARK (SUEDA-FRIKA).** [Development of Pig Iron Production at Vanderbylpark (South Africa)]. The ISCOR blast furnace plant at Vanderbylpak is Africa's largest pig iron producer with an annual production of 3.4 million tons (1986). This is the result of a productivity increase of more than 40% with the same furnace capacity over a ten-year period. The fuel consumption was reduced by about 20% in the same time period. Other cost-reducing measures have contributed to making South Africa one of the most economical sites for the production of pig iron and steel. In this paper the author describes the metallurgical developments and blast furnace modification which made these achievements possible. In German. 3 refs.

**Temperature Measurement**

**078645 USE OF A SYSTEM TO CONTINUOUSLY MEASURE PIG-IRON TEMPERATURE DURING TAPPING.** A system to continuously measure pig-iron temperature during tapping has been in use on blast furnace No. 9 at the Krivorožstal' combine since 1982. Analysis of its performance has made it possible to implement several measures to increase the accuracy and reliability of the temperature measurement. The authors made changes in the circuit of the measurement system, corrected the program for initiation of temperature measurement, and moved the pyrometric sensors and computer links into the casthouse control room. This made it possible to provide pig measurements from 1350 to 1600°C with an error no greater than 1% relative to a control thermocouple.

**078646 PIGMENT DEVELOPMENT.** Pigments for the decoration of ceramics have been used since prehistoric times and although over the centuries significant additions have been made to the potters' palette, it was not until about 200 years ago in Europe that the systematic development of ceramic pigments began. It is only in relatively recent times that a scientific approach to pigment development has been introduced into what at one time was considered to be an art. This paper describes some of the pigment research and development which is in progress with the ultimate objective of extending the color palette of the potter.

**078650 SPECTROSCOPIC INVESTIGATION OF THE ANISOTROPY OF A LIQUID CRYSTAL MATRIX DOPED WITH PHOTOSYNTHETIC PIGMENTS: EFFECT OF PIGMENT CONCENTRATION ON THE DEGREE OF MACROSCOPIC ORDER.** The macroscopic order parameters of the homogeneously aligned liquid crystal (MBBA) with dissolved photosynthetic pigments (chlorophyll a, chlorophyll b and  $\beta$ -carotene) were determined using polarized absorption, emission and Raman scattering methods. Assuming the cylindrical symmetry of the pigment orientation around the liquid crystal director, the experimental and calculated values of the order parameter were correlated by using the distribution function of the nematics. It was shown that the order parameter of the matrix is dramatically destroyed by a high chlorophyll concentration ( $3 \times 10^{-3}M$ ), whereas over a wide range of concentration the carotene did not change the matrix order. (Author abstract). 9 refs.

## Agglomeration

**078651 EXAMPLE OF SPHERICAL AGGLOMERATION OF PIGMENT IN LATEX PAINT.** Spherical agglomeration, as defined by the mineral refining industry, can result from adsorption of a surfactant and a hydrocarbon solvent onto solid particles dispersed in an aqueous medium. Bridging of the particles by the hydrocarbon leads to separation as unique, large spherical agglomerates. Such behavior was observed in a water-based latex paint where preferential agglomeration of a particular pigment, yellow iron oxide, caused an undesirable loss of tinting strength with increased shaking time. The pigment agglomerates were studied after separation by dilution and decanting. The problem was avoided by making the pigment less hydrophobic. (Author abstract) 10 refs.

## Analysis

**078652 METHODS OF DETERMINING THE STATE OF PIGMENT DISPERSION.** Three direct and three indirect methods are reported for analyzing the degree of pigment dispersion. Microscopy and sedimentation, which are well-known direct methods, and fiber optic quasi-elastic light scattering, which is a recent addition. Among indirect methods, rheological, viscoelastic and optical methods are well-known, and they have now been supplemented by methods involving the measurement of flocculation gradient and energy distribution broadening during proton or  $\alpha$ -particle scattering. All these various methods illustrate a common feature of colloid and interface science: only the combined application of several, different methods can explain how and why a dispersion behaves in a particular way. 28 refs.

USA); Eppler, Richard A. *J Am Ceram Soc* v 71 n 4 Apr 1988 p C212-C214.

## Grinding

**078655 EVOLUTION OF THE PAINT MILL.** The grinding and dispersing of pigments is the most important processing step in paint manufacturing. This article discusses how paint mills have evolved. Effective pigment grinding and uniform dispersion can be achieved using a small media mill that breaks up large pigment clusters into colloidal-size entities and distributes them evenly in the solution. A media mill consists essentially of a chamber containing a set of equally spaced disks fixed on a shaft and a motor drive. The disks can be rotated at tip speeds of 1700 to 2200 fpm. After grinding media is added to the chamber, pigment and vehicle slurry are pumped in, passing through a whirling bed of media that grinds and disperses the pigment particles. The dispersed product is then removed from the chamber through a screen that retains the media.

**Manufacture** See Also SCRUBBERS.

**078657 NEW TECHNIQUE OF PRODUCTION OF BRUNSWICK GREENS.** A new technique developed by the Regional Research Laboratory, Bhubaneswar, for the production of Brunswick Greens directly from the basic raw materials has been described. The properties of the product obtained by the new method have also been studied and compared with those of a product produced by other methods. The commercial production of these pigments still continues even though on a reduced scale due to their low cost and the shades which can not be imitated by any other formulation. The reduced production is also attributed to the availability of phthalocyanine Greens which replaced them in some applications. (Edited author abstract)

**078658 PREPARATION AND PROPERTIES OF UNIFORMLY COATED INORGANIC COLLOIDAL PARTICLES. 2. CHROMIUM HYDROUS OXIDE ON HEMATITE.** Mixed or complex colloidal matter has been of interest in various applications, such as in fabrication of composite materials. For certain uses it may be advantageous to deposit uniform layers of a given substance on the particles of another kind to achieve a modification of the surface charge characteristics and/or other properties (magnetic, optical, adsorptive, density, etc.) For instance, several processes have been developed for coating pigments. Spindle-type hematite particles of narrow size distribution were coated with uniform layers of chromium hydrous oxide by using a 'forced hydrolysis-precipitation' procedure. The coating process can be enhanced either by aging the chrom alum solution or by

pretreating it with an addition of base. The subsequent heating of such solutions in the presence of hematite 'cores' yielded uniformly coated particles if the available surface areas of the dispersed solids and the concentration of the chromium complex solutions were in appropriate ratios. Various properties of the coated solids are described. (Edited author abstract) 44 refs.

**078659 CERAMIC PIGMENTS IN THE NIO-MgO-SiO<sub>2</sub> SYSTEM.** Attempts were made to obtain new nickel-bearing greenish pigments using a completed isomorphism of magnesium and nickel in the orthosilicates of olivine group; their green coloration is due to the presence of the chromophore ion of nickel in the hexagonal (six-fold) coordination. X-ray phase analysis carried out showed that the fired materials contain only a small amount of nickel-olivine. In order to delineate the reasons for the deviation, a study was made using a heating assembly (attachment) in conjunction with the diffractometer. The results are discussed.

**078660 BIOLOGICAL MONITORING OF OCCUPATIONAL EXPOSURE IN THE CHROMATE PIGMENT PRODUCTION INDUSTRY.** A survey of occupational exposure to hexavalent chromium in chromate pigment production was undertaken in factories producing lead chromate ( $\text{PbCrO}_4$ ) and strontium chromate ( $\text{SrCrO}_4$ ). Exceptionally high levels of chromium in blood ( $387\text{-}4160 \text{ nmol l}^{-1}$ ) and urine ( $41\text{-}1250 \text{ nmol nmol}^{-1}$  creatinine) as well as skin and nasal lesions, were discovered amongst the workforce at the strontium chromate plant. These contrasted with occupationally unexposed levels of  $< 20 \text{ nmol l}^{-1}$  and  $< 1 \text{ nmol nmol}^{-1}$  creatinine, respectively, and led to the continuation of the biological monitoring programme. At the same time, improved working practices and respiratory protection equipment were introduced. A steady elimination of chromium from whole blood with a half-life of approximately 24 days was found. This elimination rate was confirmed over a 14-day period when the workforce were completely removed from exposure. (Edited author abstract). 7 refs.

**078661 INFLUENCE OF AGGREGATE STRUCTURE AND WETTING ON THE DISPERSIBILITY OF  $\beta$ -COPPER PHTHALOCYANINE PIGMENTS IN VISCOUS PRINTING INKS.** In the specific context of dispersibility of  $\beta$ -copper phthalocyanine pigments for viscous printing inks, attention is concentrated on two aspects. One is the influence of crystal growth on aggregate structure; the other is the influence of abiethyl resin additives on aggregate structure and wettability. It is shown that the aggregate structure is, however, extensively penetrated and opened up by organic liquids at room temperature and higher. These liquids gain access to surfaces inaccessible to nitrogen. Crystal growth then occurs to produce rod-shaped  $\beta$ -form crystals. The extent of crystal growth is dependent upon the strength of interaction of the liquid with the copper phthalocyanine surface. Above a critical region for the heat of interaction of  $104$  to  $106 \text{ mJ m}^{-2}$  extensive growth occurs. At higher levels of growth, a second growth mechanism becomes evident: this involves side-by-side fusion of  $\beta$ -form crystals and results in lower crystal axial ratios. 12 refs.

Mixing See COATINGS—Production.

Modification See Also TITANIUM OXIDES—Modification.

**078663 SURFACE TREATMENT OF PIGMENTS.** Coated pigments which possess a high affinity for binder molecules and preserve such affinity into the dry film will exhibit a high degree of dispersion in the film and favorable properties such as gloss, color strength, chroma and better light- and weather-resistant properties than the corresponding untreated pigments. This arises from the improved wettability achieved since better wetted pigment particles are also shielded to a greater extent by the binder molecules against the adverse action of light and weather. In addition, the film as a whole will exhibit a lower permeability towards water and oxygen and a higher durability and mechanical properties in contrast to the situation where 'pigment wetting' is lower. The surface treatment of pigments provides a powerful method for achieving this goal. 30 refs.

## Optical Properties

**078664 OZONE FADING OF NATURAL ORGANIC COLORANTS: MECHANISMS AND PRODUCTS OF THE REACTION OF OZONE WITH INDIGOS.** Indigo, dibromoindigo, and colorants containing thioindigo and tetrachlorothioindigo were exposed in the dark to dry, purified air containing ozone (10 ppm) for 4 days, and the exposed samples were analyzed by mass spectrometry. Under the conditions employed, indigo and dibromoindigo were entirely consumed, and the major reaction products were isatin and isatoic anhydride from indigo and bromoisatin and bromoisatoic anhydride from dibromoindigo. Thioindigo and its chloro derivative also reacted with ozone, though at a slower rate; the corresponding substituted isatins and anhydrides were tentatively identified as reaction products. These results can be rationalized in terms of a mechanism involving electrophilic addition of ozone onto the unsaturated carbon-carbon bond. (Author abstract) 15 refs.

Grosjean, Daniel (California Inst of Technology, Pasadena, CA, USA); Whitmore, Paul M.; Cass, Glen R.; Druzak, James R. *Environ Sci Technol* v 22 n 3 Mar 1988 p 292-298.

**078665 GLOBAL OPTIMIZATION IN AN INVERSE PAINT-OPTICS PROBLEM.** Pigment-system optics (PSO) has applications of direct and inverse types. The direct class involves determining the optical and color characteristics for systems from those of the components. By inverse problems, one means the determination of component characteristics to provide overall characteris-

tics for the system as a whole. The latter are optimizations, since one needs to determine the optimum values for the components to minimize the target function. The objective of this work is to choose an effective global-optimization method for that purpose. Four algorithms were selected. One of the simplest global-optimization ones is complete search and involves search on an LP grid, which is an approximation to a grid with uniformly distributed nodes, while Torn's algorithm is based on random search with cluster analysis to identify local minima, whose main advantage is its speed, since the auxiliary calculations consume only a little time. The other two algorithms are based on statistical models: the simplified Bayes one and an axiomatically constructed statistical simulation method. The authors conclude that the axiomatic algorithm is the most effective, and it was selected for calculating mixtures with given spectral and color features. The modified variable-metric algorithm was used as the local-optimization one to refine the global search results. 14 refs.

## Performance

**078668 EFFECT OF FIBER BEATING ON  $\text{TiO}_2$  PIGMENT PERFORMANCE.** The retention of  $\text{TiO}_2$  pigment and its light-scattering efficiency were evaluated on handsheets formed from fibers beaten to different degrees of freeness. Cationic  $\text{TiO}_2$ , which deposits on anionic fibers, was used to eliminate the effect of pigment flocculation caused by retention aids. The degree of beating had only a small effect on the amount of pigment that was deposited on fiber and retained during sheet preparation when less pigment was added than required for full fiber coverage. On the other hand, beating considerably affected the apparent light-scattering efficiency of the pigment, which increased progressively with beating level. It is assumed that the fibrils and fines generated by beating are prevented from collapsing onto the fiber surface by the pigment particles and that this provides an additional source of light scattering. (Author abstract) 15 refs.

## Photochemical Reactions

**078669 IMPROVEMENT IN THE LIGHTFAST-NESS OF DYED AND PIGMENTED MATERIALS-PART 2: EFFECT OF SINGLE OXYGEN QUENCHERS ON THE PHOTOSTABILISATION**

**OF ORGANIC PIGMENTS IN SOME COATING FILMS.** The effect of some singlet oxygen quenchers on the photostabilisation of C.I. Pigment Red 3 and C.I. Pigment Red 49 in coating films prepared from cellulosic lacquer, alkyd resin and polyurethane-type paints was examined. The rates of photodegradation of the pigments were retarded by adding effective singlet oxygen quenchers, such as nickel diethyldithiocarbamate, nickel bis(dithiobenzil) and nickel bis(N-n-dodecylsalicylaldimine). The coexistence of an equal amount of the singlet oxygen quencher and a hindered phenol (good radical scavenger) was effective in improving the light resistance of the pigments, but the addition of a hindered phenol alone was not effective. (Author abstract). 31 refs.

## Synthesis

**078672 PECULIARITIES OF THE SYNTHESIS OF CERAMIC PINK PIGMENT.** The authors studied the possibility of synthesizing rose colored pigments on the basis of corundum with additions of  $\text{Mn}_2\text{O}_3$ ,  $\text{Fe}_2\text{O}_3$  and  $\text{Cr}_2\text{O}_3$  in amounts of from 1 to 10%. To reduce the synthesis temperature of the pigments we added boric, alkali, and phosphate compounds to the original mixtures. The results of the determination of the color characteristics of the pigments with the various mineralizing agents are presented. The investigations showed that adding 10-20% calcium borate ensures a high tone purity (25%). The modifying action of borate is caused by the capacity of the ions of the alkaline earth metals to reinforce the deformation of the electron shells of the chromophores. However, during the production of colored glazes we noted a reduction in the tone purity. It is known that zinc oxides stabilizes the color of pigments. An addition of 5-15%  $\text{ZnO}$  led to the formation of graphite,  $\text{ZnAl}_2\text{O}_4$ , and contributed to color stability of the pigment in the glaze melts. The investigation showed that the optimum

firing temperature is 1200°C at which color stability is provided with the maximum tone purity of pigment. 5 refs.

**078674 COLOUR AND CONSTITUTION RELATIONSHIPS IN ORGANIC PIGMENTS. PART I. MONOAZOACETOACETANILIDES.** Monoazoacetanilides provide some of the most important classical organic pigments in the yellow to orange shade area for a range of applications. As a first step in attempting to establish the color and constitution relationships in this series of products, a range of monoazoacetanilides was synthesized and their uv/visible spectral behavior in solution investigated. PPP molecular orbital calculations, using the generalized set of parameters approach, were refined by parameter optimization to provide an excellent correlation between calculated and experimental  $\lambda_{max}$  values for the principal absorption band, and in addition there was generally good qualitative agreement between molar extinction coefficients and the calculated oscillator strengths. The nature of the electronic excitation process is discussed in terms of the calculated changes in  $\pi$ -electron charge densities. (Author abstract) 28 refs.

**078675 NEW HETEROCYCLIC PIGMENTS.** The discovery of a novel family of heterocyclic compound pigments, 1,4-diketopyrrolo(3,4-c)pyrrole, called the DPP is discussed. An attempt is made to rationalize their properties in terms of their solid state structures. Various mechanisms of formation of DPP are described and the chemistry, especially bearing on the synthesis and development of pigmentary forms of DPP, also is briefly outlined. (Edited author abstract) 7 refs.

**078676 SQUARINE CHEMISTRY. SYNTHESIS, STRUCTURAL CHARACTERIZATION AND XEROGRAPHIC PROPERTIES OF MIXTURES OF HALOSQUARINES.** A number of mixtures of halosquarines have been synthesized by co-reacting mixtures of N,N-dimethylaniline and N, N-dimethylhaloaniline with dibutyl squarate in water-saturated 1-butanol. Yield decreases as the concentration of N, N-dimethylhaloaniline increases and this decrease is attributable to the low reactivity of N,N-dimethylhaloaniline. This low reactivity is also revealed in the lower than expected halogen incorporation in all the mixtures studied. The chemical composition of each mixture was studied by high-resolution proton NMR spectroscopy and mass spectrometry. The merit of these two techniques in the identification and quantification of individual squarines in the mixtures is presented and discussed. The xerographic properties of each mixture were studied by xerographic photodischarge technique in bilayer photoreceptor devices. (Edited author abstract) 21 refs.

**078677 SYNTHESIS OF A BLUE ZIRCON PIGMENT.** Thermal analysis (DTA, DTG, TG), calcination of the starting mixture in an electric furnace at various temperatures and for different periods of time, and tabletting (marking) experiments have been used to evaluate the reactions involved in the synthesis of the blue zircon pigment  $Zr_{1-x}V_xSiO_4$ . Three industrial samples of  $ZrO_2$  were evaluated as the starting zircon components. The temperature of the pigment synthesis was determined for each of three samples, their different reactivity explained, and the mechanism and kinetics of the pigment formation investigated. (Author abstract) 31 refs.

Trojan, M. (Inst of Chemical Technology, Pardubice, Czech). *Dyes Pigm* v 9 n 3 1988 p 221-232.

**078678 PIGMENTS HAVING A CORDIERITE TYPE STRUCTURE.** Based on the method suggested by S.G. Tumanov, pigments were obtained of different colors having the willemite, mullite, spene, and zircon-like structures etc. The possibility of synthesizing such pigments for the structures of different types was confirmed by the thermodynamic analysis of the energy state of the process of evolution (formation) of crystalline phases. Differently colored ceramic pigments based on cordierite  $2 MgO \cdot 2 Al_2O_3 \cdot 5 SiO_2$  have been synthesized by equimolecular substitution of magnesium oxide with the oxides of other metals. It can be concluded that the synthesis reaction of the nickel-bearing cordierite is characterized by large negative values of the Gibbs energy as compared to the reaction of formation of nickel spinel. 5 refs.

**078679 SYNTHESIS OF A PINK ZIRCON PIGMENT.** A pink zircon pigment of the inclusion type,  $(ZrSiO_4)_{1-x}XFe_2O_3$ , has been synthesized by a thermal process from the starting oxides  $ZrO_2$  and  $SiO_2$ . Green vitriol (ferrous sulphate) or ferric oxide-hydroxide has been used as the chromophore (source of the inclusions). The reactions in the synthesis have been followed by thermal analysis, by analysis of the products prepared under isothermal conditions at various temperatures and during various reaction times in an electric furnace, and by tabletting (marking) experiments. Two types of commercial  $ZrO_2$  have been used, both of them being raw materials for the industrial production of zircon pigments. The reactivity of these oxides has been evaluated, the conditions of the pigments synthesis have been determined and the reaction mechanism and kinetics have been investigated. (Edited author abstract) 29 refs.

**078681 PRINCIPLE OF SPECTRAL EVALUATION IN PIGMENT TESTING. A REVIEW OF 20 YEARS' APPLICATION OF A SUCCESSFUL METHOD.** The development and applications of the Principle of Spectral Evaluation in pigment testing is

described in this paper. The 'principle of spectral evaluation' permits mathematical simulation of the visual evaluation of the adjustment of two sample coatings by combining elements of Kubelka-Munk theory and colorimetry. When determining the hiding power, that film thickness of the paint film is found at which the contrast background just disappears to the eye of the observer. The reciprocal of the thickness of this hiding layer gives the hiding power as a yield property, since it specifies the area which can be hidden by coating with one liter of this paint. Some of the new improvements are discussed. 23 refs.

Voelz, Hans G. (Bayer AG, Krefeld-Uerdingen, West Ger). *Prog Org Coatings* v 15 n 2 Jun 26 1987 p 99-124.

**078682 KAOLIN-BASED CERAMIC PIGMENTS.** The purpose of this investigation is to determine the maximum amount of kaolin based on which one can produce pigments and to examine the role of chromophores and modifying additives. For subsequent experiments we selected  $ZrO_2$ ,  $SnO_2$  and  $TiO_2$  as the modifying oxide additives since they are known to impart thermal stability and chemical resistance to the pigments. The optimum synthesis temperature was 1200°C. Introducing 10-60%  $Fe_2O_3$  makes it possible to obtain brown colored pigments. The presence of chromium oxides (5-30%) in the kaolin-bearing systems led to an increase in the firing temperature up to 1250°C because of the refractoriness of  $Cr_2O_3$  and imparted greenish coloration to the pigments. It is shown that kaolin-based pigments possess improved color characteristics and their application is economical. 6 refs.

**078683 CROWDING AND SPACING OF TITANIUM DIOXIDE PIGMENTS.** For geometric reasons, the maximum size of extender particles intended to improve hiding is limited by rutile size and volume concentration. Maximum size of hiding effective extender is small, less than commercial products and dispersion processes can deliver. Hiding improvements can, however, be obtained through uniform spacing of rutile by coatings no rutile particles. The hiding power advantage of such product over conventional rutile could be as much as 10%. 15 refs.

## Toxicity

**078686 MIXED METAL OXIDE COLORS ARE STABLE, LOW IN TOXICITY.** Mixed metal oxide colorants are a class of synthetic mineral pigments to be watched owing to their low toxicity combined with chemical stability and excellent lightfastness. These inert colorants are becoming available in a greater range of colors with improved working properties. The recent, heightened research activity on the development of new ceramic products has simultaneously resulted in new ceramic processing technology that includes improved high temperature kilns for calcining and improved methods for controlling particle size and uniformity. Both are very important properties in the manufacture of quality pigments.

**078687 REVIEW OF METHODS FOR ESTIMATING PILE CAPACITY.** The first phase of an investigation of methods for construction control of pile driving and determination of pile capacity has been completed for the Washington State Department of Transportation. A literature review covering the use of dynamic pile driving equations, wave equation methods, and pile analyzers has been conducted. In addition, a survey of current practices by state transportation departments has been completed. The literature review has shown that dynamic formulas provide the least reliable pile capacity predictions. Of the numerous formulas studied, no single dynamic pile driving formula was found to be superior to all others. (Edited author abstract) 26 refs.

**078688 IHC HYDROHAMMER: PILE HAMMER - CUM - ROCKBREAKER.** The hydrohammer which may be described as the third generation of hydraulic pile hammers was developed for piling in air or under water. The special ram which forms part of the piston rod, is mounted in the totally-enclosed housing and runs in sealed, oil-lubricated bushes and this bearing arrangement affords low friction and wear. Hydraulic fluid flows via the hose connection and the valves in ring to the underside of the piston in the cylinder. The pressure of the fluid lifts the ram. On the downward stroke, additional energy is delivered to the ram, producing an acceleration of 2 g. The maximum stroke of 1 m thus corresponds to a fall height of 2 m. The electronic control system, which is easy to operate, contributes in large measure to the reliability and versatility of the Hydrohammer. Its advantages for underwater rockbreaking include: controllability; optimum energy transfer; safety.

## Computer Applications See FOUNDATIONS—Piles.

**Design** See PILES—Driving.

## Hydraulic Drive

**078689 PILING EQUIPMENT.** Recent developments in equipment for driven and bored piles have been the introduction of hydraulically driven machines with, in some areas, the use of sophisticated control systems. This has resulted in more efficient pile installation and often the reduction of men needed on site. Hydraulic pile hammers are now being increasingly used to drive steel sheet piles and bearing piles. Hydraulic piling vibrators are now widely used for driving steel sheet piles, open tube piles, H beams, and casings for bored piles. Hydraulic pile driving rigs are now used for driving both bearing and steel sheet piles.

Rawlings, Peter (Rawlings Collerton, Engl). *Civ Eng (London)* Aug 1987 p 19.

**078690 HYDRAULIC HAMMERS SET THE TREND IN PILING.** There is no doubt that pile driving is moving in a general direction towards more environmentally acceptable hammers. If this can be coupled with a more economic pile installation rate then we should have the answer to most of the problems today facing the contractor in an urban environment. Because of the trend in recent years toward hydraulically operated site equipment including cranes, the obvious development was also in this direction. The hydraulic pile hammer is now with us and to understand the reasons for its development we should examine its advantages.

Redhead, David (BSP Int Foundations Ltd). *Highways (Croydon Engl)* v 55 n 1930 Oct 1987 p 14, 26.

## PILES

**078691 ITERATIVE ANALYSIS OF PILE-SOIL-PILE INTERACTION.** Consistent formulations of direct and iterative methods of pile group analysis are presented. The iterative methods are derived from the same equilibrium and compatibility equations as the direct methods but are cast in different forms. These new iterative methods highlight the shortcomings of some existing iterative methods of analysis, although conceptually they are similar. Unlike the direct methods of analysis in which the stiffness matrix of the pile group system is generally fully coupled, the individual pile stiffness matrix can be uncoupled in the iterative methods and requires only a minimal amount of computer core storage. The accuracy of the iterative methods is compared with that of the direct method, and generally good agreement can be obtained. (Edited author abstract) 24 refs.

Chow, Y.K. (Natl Univ of Singapore, Singapore). *Geotechnique* v 37 n 3 Sep 1987 p 321-333.

**078692 UPLIFT CAPACITY OF DRIVEN PILES IN SAND.** Driven piles widely used in civil engineering construction are sometimes subjected to uplift forces. Available methods of estimating the uplift capacity of piles show wide variations. A theoretical method for predicting the uplift capacity of driven piles, considering the effect of driving on the properties of surrounding soil, has been proposed. Predictions from the proposed method show agreement with the experimental results on model and field piles. (Author abstract) 12 refs.

Pise, P.J. (IIT, Kharagpur, India); Chattopadhyay, B.C. *J Inst Eng India Part CI* v 68 n 2 Sep 1987 p 89-91.

**078693 PILE DISPLACEMENT DUE TO TENSILE LOADS.** Displacement of a pile subjected to tensile load is analyzed. The pile is treated as rigid and soil as a semi-infinite elastic half-space. The displacement influence coefficient,  $I$ , for the pile is evaluated as a function of the length to diameter ratio of the pile, and the Poisson's ratio of the soil. The values of  $I$  are about 25-30 percent more than those for compressive loads. It is now possible to interpret tension tests on piles for the modulus of deformation of the soil. Two case studies analyzed show comparable values of the modulus of deformation of the soil evaluated from different in situ tests. (Author ab-

stract). 5 Refs.

## Bearing Capacity See Also PILE DRIVERS.

**078694 CASE HISTORY ON PIPE PILE INSTALLATION.** In current practice, pile foundation design is based on a general understanding of pile-soil interaction during installation and superstructure-pile-soil interaction after construction. The pile design is a reflection of experience, precedent and judgment for normal piling practices of working load capacities up to approximately 100 tons with corresponding ultimate capacities up to 200 tons. For higher capacity piles, pile design is even less predictable. In particular, the feasibility of pile installation is an important design consideration that must be given the proper attention. (Edited author abstract)

Parola, Jerry F. (Case Int Corp, Roselle, IL, USA). *Deep Found J* Spring 1986 p 53-64.

**078695 MODELING OF BEARING CAPACITY OF PILES IN CLAYS.** To determine the bearing capacity of piles, in the modern construction practice wide use is made of soil testing methods by means of standard piles and probes 36-150 mm in diameter, that is, pile models of a different scale. At the Dal'NIIS Institute, investigations have been carried out to establish the relation between the limit strengths of pile models having different scales. The investigation of such models in clays, which is connected with certain difficulties, has been carried out in the USSR for the first time. The results obtained make it possible to substantiate the general laws of modeling of the bearing capacity of piles having any shapes. 2 refs.

**078697 ULTIMATE LATERAL PILE CAPACITY IN TWO-LAYER SOIL.** Expressions are derived for the ultimate lateral load capacity of a pile in a two-layer cohesive soil profile. Both free head and fixed head piles are considered and in each case, dimensionless solutions are given for failure of the supporting soil ('short pile' failure) and failure of the pile itself ('long pile' failure). Some parametric solutions are plotted and an illustrative example is given to demonstrate the application of the analysis. (Author abstract) 3 refs.

Poulos, H.G. (Univ of Sydney, Aust). *Res Rep Univ Sydney Sch Civ Min Eng* n R503 Aug 1985 25p.

**078698 SOIL IMPROVEMENT WITH GRANULAR PILES.** An effective method of construction of granular piles as an economical alternative to 'stone columns' using vibroflot has been developed. The technique uses labour oriented technology based on indigenous know-how, avoiding import of costly equipment suiting to the developing countries. In the present investigation a new concept of skirted granular piles has been advanced. Full scale in situ tests have been carried out at four different sites on both virgin and soils improved by

granular piles, by cating plain, individually and collectively skirted granular piles in single and in group. The effectiveness of installing granular piles for soil improvement and benefit of using skirt individually or collectively have been fully demonstrated, by noting a significant improvement in bearing capacity. A simple method of predicting the ultimate capacity and settlement of granular piles installed in weak sub-soil deposit has been proposed. (Edited author abstract) 19 refs.

**078699 EVALUATION OF PILE BEARING CAPACITY FROM RESULTS OF STATIC PENETRATION TESTS USING A PROBABILISTIC APPROACH.** One of the most important objectives of the use of static penetration tests of soils is to obtain initial data for analysis of the bearing capacity of piles. When use is made of data from static penetration tests it is advisable to increase the calculated bearing capacity of piles by about 25%. It is recommended to carry out static penetration tests in all the design stages to determine the bearing capacity of piles up to 15 m long. This paper considers the possibility of a probabilistic approach to the evaluation of the bearing capacity of a driven friction pile from static penetration test results. 4 refs.

Divinskii, M.L. *Soil Mech Found Eng* v 24 n 4 Jul-Aug 1987 p 133-137.

**078700 CHANGE IN BEARING CAPACITY OF BORED-CAST-IN-PLACE PILES UNDER SALT LIxivATION FROM SOIL BASE.** For construction on saline and gypsum soils, in many cases it is advisable to use reliable, economical pile foundations. In this article, the writers present results of static tests of bored-cast-in-place piles of gypsum clays, which were carried out for the first time in order to determine the changes in the bearing capacity of a pile for soil desalination, to study the factors which govern these changes, and to work out methods of evaluation of the bearing capacity of piles under such soil conditions. The tests were performed at a test site located in the arid zone of the Uzbek SSR, the soil base of which consisted of proluvial-deluvial gypsum loams and gypsum sandy loams. 2 refs.

Petrukhin, V.P. (Scientific-Research Inst of Bases & Underground Structures, USSR); Gemmerling, V.O. *Soil Mech Found Eng* v 24 n 4 Jul-Aug 1987 p 144-148.

**078701 REASONABLE APPROACH TO DETERMINATION OF BEARING CAPACITY OF PILE.** Bearing capacity of pile is usually determined by field test. The results of few test piles are conventionally regarded as a design basis for all other piles in the same site. However, the practical experience of pile test shows that quite a large deviation of the actual bearing capacity of piles exists. Based on the test data of 71 cast-in-place piles the following conclusions have been drawn: 1. It is evident that the test data of pile load tests scatter over a wide range and the maximum bearing capacity can be twice as large as the minimum one. 2. The reasons that cause dispersion of bearing capacity values are: non-homogeneity of soil; the differences in real pile length and diameter; the quality of casting concrete; the thickness of sludge directly beneath the pile bottom as well as the verticality of pile shaft. Thus, the dispersion of bearing capacity is closely related to the construction technology. 3. The real value of pile bearing capacity is a random variable, therefore it should be handled by means of mathematical statistics. (Edited author abstract) 2 refs. In Chinese.

Xu, Youzai (Central Research Inst of Building & Construction, China); Liu, Xingman. *Tumu Gongcheng Xuebao* v 20 n 2 May 1987 p 69-77.

**078702 STATIC-PENETRATION DETERMINATION OF THE BEARING CAPACITY OF PILES IN PLASTIC-FROZEN SOILS.** Field methods, which make it possible to determine the frozen-soil conditions of construction sites quickly and rather reliably, have recently come into increasingly broader practical use in

geocryologic-engineering surveys. One of the most promising of these methods is static penetration by series-produced domestic apparatus, S-832M, SP-59B, and SP-72. Stabilization of penetrometer settlement will signal that the penetrometer-soil system has come to equilibrium. We can then assume that the strength  $q_p$  corresponding to the stabilized deformation of the penetrometer will be close to the soil's long-term ultimate strength. Use of the method of static penetration during geologic-engineering surveys will make it possible to investigate the strength properties of soils in greater detail, and, in turn, to improve the reliability and economy of the design solutions employed for pile foundations. Moreover, a partial reduction in the number of static pile tests with their replacement by static penetration makes it possible to reduce significantly the labor outlays, duration, and cost of these operations. 10 refs.

**Calculations**

**078704 HORIZONTAL BELASTETE STARRE BOHRPFAEHLN IN BOESCHUNGEN.** [Horizontally Loaded Rigid Bored Piles in Slopes]. A method of calculation for rigid bored piles in sloping ground is presented. The method is based on Coulomb's classical thrust theory and has been extended to cover restricted compression areas. The method produces economical pile lengths which, although considerably lower than those determined to date, are still stable. The reaction forces of the soil actually present are taken into consideration, and the soil resistance is calculated as the minimum value together with the corresponding sliding joints. The soil resistance is made up of plane, spatial and lateral elements. The progressive fracture is defined as the angle  $\omega$ . The method can be extended to include different soil types and slope inclinations with the aid of further model tests and trial loads. (Edited author abstract). 10 Refs. In German.

**078705 CONTINUOUS FLIGHT AUGER PILING AT ST ENOCH SQUARE, GLASGOW.** At the St. Enoch Square Development in Glasgow, continuous flight auger piles were selected for those foundations close to existing structures of tunnels. Two trial piles were constructed and test loaded in advance of constructing the works piles. Under test load, the concrete shaft of each trial pile failed at less than 1.75 times the pile working load. This article describes the construction and investigation of the failed trial piles, and the revised construction

method implemented in which monitoring the volume of concrete pumped into the pile became the principal factor in controlling pile construction.

Couldery, P.A.J. (Ove Arup & Partners Scotland); Fleming, W.G.K. *Ground Eng* v 20 n 6 Sep 1987 8p between p 17 and 28.

**078706 PERFORMANCE OF DRIVEN PRE-STRESSED CONCRETE PILES.** The performance of pre-stressed concrete piles in various ground conditions has been examined and the results described so that the suitability of this type of pile can be judged for the different ground conditions encountered in Hong Kong. It has been found that pre-stressed high-strength concrete piles can penetrate crushed-rock reclamation filling and alluvial cobble layers, but special shoes should improve driving in these hard conditions. In medium-soft ground, such as completely decomposed granite, piles have sometimes stopped shorter than expected in strata with relatively low blow-counts in the Standard Penetration Test (SPT 'N' values.) Loading and integrity tests have demonstrated completely satisfactory load bearing capacity. Investigations after driving the piles have shown that significant 'densification' of the ground had occurred for several metres around and below the piles. (Edited author abstract) 12 refs.

Evans, G.L. *Hong Kong Eng* v 15 n 3 Mar 1987 p 9-14, 16.

**078707 PRACTICAL GUIDANCE ON THE USE OF INTEGRITY TESTS FOR THE QUALITY CONTROL OF CAST-IN-SITU PILES.** The most common integrity test measures, in various ways, the dynamic response of the pile shaft and require access only to the pile head. These tests can provide a valuable measure of quality control, but in common with all non-destructive test methods, they have serious limitations which must be recognized before they are specified. This paper describes the physical principles of the most common pile integrity tests and quantitatively defines their acoustical capabilities and limitations. The relationship between the acoustical and structural significance of faults in the integrity of cast-in-situ piles is discussed, and guidance is given on the assessment of pile integrity test results. 8 refs.

**078708 PALI RADICE: THEIR USES IN STABILISING EXISTING RETAINING WALLS AND CREATING CAST-IN-SITU RETAINING STRUCTURES.** When used for stabilization, the piles are installed through the existing structure thereby achieving a direct connection between the foundation and a competent underlying subsoil stratum providing the structure with 'roots' and hence giving the piles the proprietary name. The principal of constructing alternately raking piles through conventional footings and column based has been developed and extended to treat complex foundation engineering problems where structures are subjected to more complex externally applied forces. Their application to the stabilization of existing retaining walls offers a versatile solution which minimizes the necessity for any conventional civil engineering works. A recent example of the successful use of this system was at Weston Point Docks, Runcorn. The Fondedile process known as a Reticulated Pali Radice Structure is designed to transform a naturally heterogeneous soil into a composite material with a controllable structural behavior. This technique was employed at the Dartford Tunnel Southern Approach Road. Both applications are discussed in the article.

Attwood, S. (Fondedile Foundations Ltd). *Ground Eng* v 40 n 3 Mar 1987 p 23-24, 26-27.

**078709 INSTALLING PILES WITHOUT IMPACT - A CASE HISTORY.** The conventional method of installing piles is by driving. The impact of driving imparts vibration to the adjoining soil. As a result, loose and medium compact sands and silts tend to become consoli-

dated. The consolidation causes structures to settle. The settlement in turn leads to cracks in buildings. The subject of this paper is a case history of avoiding the pile driving vibrations and thus sidestepping the vibration induced damage by changing the piles in the potentially sensitive areas during construction from H-piling to auger-cast piling. This was the first application of auger cast piles in the City of New York. The project was the Hamilton Avenue Marine Transfer Station in Brooklyn, New York.

Kald, Lembit (Hayden-Wegman Inc, USA). *Munic Eng J* v 73 Summer 1987 p 1-11.

**078710 LE PROCEDE STARSOL. [STARSOL Process].** The French pile market can be divided in three parts: the small piles (with a diameter up to 0.20 m); the medium-size piles (with a diameter between 0.40 m and 1.20 m); the strip piles (with a cross section area more than 1 m<sup>2</sup>). The medium segment, the most important, is dominated both by the classic auger and the continuous flight auger. A new equipment, 'STARSOL', has been set up, which combines a continuous flight auger, a tremie pipe and a cleaning system. Usual diameters vary between 0.50 and 1.00 m. The maximum depth is 30 m. This tool presents numerous advantages: penetration capacity in hard layers (30 to 50 MPa); drilling speed; no temporary casing, no slurry; concreting with a tremie pipe and under pressure; concreting and spoils extraction speeds; possibility to set reinforcement frames 18 m deep, as well as tubes for later sonic control. (Edited author abstract) In French.

Bollinger, Karl; Chagnot, Philippe; Sage, Daniel. *Travaux Suppl* Mar 1988 p 7-13.

**078711 CONCRETE IN PILING.** Displacement piles are formed by driving materials into the ground, thus displacing the soil. These materials can be timber, steel, but more commonly reinforced concrete. Concrete displacement piles can either be totally precast or a displacement method is used either by driving steel tubes or concrete shells to form a void which is then infilled with reinforced concrete. Non-displacement piles can also be called replacement piles, as soil is extracted from the ground and replaced by concrete which is subsequently steel reinforced. In general they fall into two main categories: where a void is formed by either percussive boring, rotary boring or drilling and the void infilled as in the case of displacement piles; or continuous flight augered (CFA) piling where a bore is formed with a hollow stemmed flight auger.

**078712 GALVANIC CORROSION OF COPPER-NICKEL SHEATHED STEEL PILING.** A study was conducted to determine the extent of galvanic corrosion that would be caused by copper-nickel sheathing of offshore steel platforms. The study investigated the effects of selected steel-to-CuNi area ratios on the magnitude and distribution of the galvanic current. One-year seawater exposure tests were conducted near Ocean City, NJ. The results the maximum galvanic corrosion rate of the steel will be between 0.2 and 0.3 mm/y immediately next to the sheathing. The galvanic attack will be confined primarily to the first few meters of piling near to the sheathing. Beyond this, the intensity of galvanic attack will decline. (Edited author abstract)

**078713 TWO-YEAR RESULTS OF LONG-TERM, COPPER-NICKEL SHEATHED PILING STUDIES.** A series of cylindrical steel piling sheathed with copper

alloy UNS C70600 were exposed in Banks Channel at Wrightsville Beach, North Carolina in 1983 to provide long-term base line data on the corrosion and biofouling behavior of insulated and directly welded sheathing techniques. After a two-year exposure, one series of piling were removed and evaluated. Insulated sheathed piling exhibited a minimal amount of biofouling attachment and unprotected piling with directly welded sheathing showing no accelerated corrosion of the adjacent steel. This paper presents the techniques used and the results after the first two years of exposure. (Author abstract).

**Deformation** See Also BRIDGES, HIGHWAY—Abutments.

**078714 ON THE BUCKLING OF SLENDER PILES.** The published analyses of axially loaded piles are based on the notion that the buckling load is  $P_{cr}$ , the so-called critical load that is obtained from a linear eigenvalue problem. The purpose of this paper is to show that generally this assumption is not justified for slender piles. Since the main aim of the presentation is to clarify the basic features of the pile buckling phenomenon, and to show how they are related to the various buckling analyses, this study is conducted on a simple model that exhibits the essential buckling mechanism of the pile but is amenable to an exact nonlinear analysis. One presented analysis is based on the common assumption that the lateral soil resistance increase linearly with the lateral displacement. Another analysis assumes that the lateral resistance stiffens nonlinearly with increasing pile displacements. Thus, for the stability analysis of slender piles, the actual soil response to lateral pile displacements is needed. (Edited author abstract). 10 Refs.

## Design

**078715 STATE OF THE ART FOR DESIGN AND CONSTRUCTION OF SAND COMPACTION PILES.** Sand compaction piles can be used to improve marginal sites for stability, liquefaction, and settlement applications. They have been employed extensively in Japan for many years to improve land reclaimed from the sea. The advantages and disadvantages of using sand compaction piles are compared with other vibro-compaction techniques such as stone columns. Methods are described for construction of sand compaction piles on land and over water. Design theories are given for the utilization of sand compaction piles at sites underlain by both cohesionless and cohesive soils. For sites underlain by cohesionless sands, procedures are presented for estimating the increase in standard penetration resistance in both the sand compaction pile and the surrounding sand. Finally, typical applications of sand compaction piles are described, and practical design criteria and practices are given. (Edited author abstract) 20 refs.

**078716 UPLIFT CAPACITY OF CAST IN SITU BORED PILE IN COHESIONLESS SOIL.** Capacity to withstand uplift forces by cast in situ bored piles is normally neglected by the designers. The theoretical basis has long been developed by the soil scientists in working out the safe capacity of such piles. Till recently actual use of such piles being designed against tension forces are not common. This paper discusses in detail the load displacement behavior of piles under upward load with particular reference to piling work done in a steel plant construction in Libya. It has been observed during the course of investigation on working piles of various diameter that even the straight piles on predominantly cohesionless soil resting on bed rock can sustain a considerable upward pullout force. (Author abstract)

**078717 IMPACT OF RECENT CHANGES IN THE API RECOMMENDED PRACTICE FOR OFFSHORE PILES IN SAND AND CLAYS.** The publication of the 15th Edition of the American Petroleum Institute (API) Recommendations in 1984 changed the guidelines for the design of piles in cohesionless (sand) soils and, in particular, the design of piles under tensile loading. Subsequently, the 17th Edition also provided revised recommendations for the design of piles in cohesive (clay) soils. This paper quantifies the changes that may occur as a result of the application of these revised procedures and relates them to the factors of safety generally applied to the design of the foundations for offshore structures. Computed capacities are compared with the results of relevant pile tests. 18 refs.

**078718 FROM THEORY TO PRACTICE IN PILE DESIGN.** The procedures used for pile design are classified into three categories: empirical, simplified but theory-based, and site-specific advanced theory-based methods. The various aspects of pile behavior which may need to be considered are reviewed and design procedures in each category are reviewed for each aspect. In many cases involving conventional loadings, the second category of design procedure is often quite adequate, but for problems involving special loading conditions, such as cyclic loading or loading arising from soil movements, the use of more sophisticated methods of analysis may be necessary to obtain an economical and safe design. Examples are presented to illustrate the use of each category of design in actual field cases. (Author abstract). 138 Refs.

## Driving

**078719 CRANE BOOM LOADINGS FROM PILE DRIVING.** Piles are being driven in longer sections and ever increasing weights. The reasons for these increases are purely economic. Loads and stresses from pile driving are increasing from heavier piles and more powerful hammers. Stresses can be dangerous to equipment stability. Equipment developer MacKinnon tells how to compute stresses for all positions of the crane boom and angles of pile batter. (Edited author abstract)

MacKinnon, Alan G. (Foundation Equipment Corp, Dover, OH, USA). *Deep Found J* Spring 1986 p 29-51.

**078720 ANALIZA RUCHU PALA ZAGLEBIANEGO W GRUNT PRZEZ URZADZENIE WIBRACYJNO-UDERZENIOWE O ZLOZONYM WYMUSZENIU. [Analysis of the Motion of a Pile Driven into the Ground by a Vibration-Impact Machine Causing Complex Excitation].** The motion of a pile driven into the soil is analyzed under the assumption that it performs vibrations in the axial direction and rotates in the plane perpendicular to this direction. The soil is assumed to act on the point of the pile as an elastic-viscoplastic medium and exerts dry and viscous friction forces on its lateral surfaces. Theoretical results obtained with a computer agree fairly well with experimental data. (Edited author abstract) In Polish. 11 refs.

Mituta, Aleksander; Raniszewski, Jozef. *Rozpr Inz* v 35 n 1 1987 p 95-112.

**078721 PILE DRIVING BY JACKING UNDER RECONSTRUCTION CONDITIONS.** The increase in the work volumes under reconstruction of buildings and structures, connected with the construction of pile foundations under constrained conditions near existing buildings, calls for improvement of the pile driving methods. The

authors have proposed a new method based on jacking of piles by means of hydraulic cylinders through openings in cap-slabs or wide strips constructed as a prefabricated-cast-in-place alternative before the start of pile driving. In this process, the forces are transmitted through the lateral surface of the pile, or its end, and the jacking reactions are resisted by the weight of the slab or strip. 2 refs.

Novikov, M.F.; Pushkarevich, V.S. *Soil Mech Found Eng* v 24 n 2 Mar-Apr 1987 p 55-58.

**078722 DEVICE FOR CONTROL OF PILE DRIVING VERTICALITY.** Piles occupy an important place in the construction industry, and their overall volume increases continually. At the same time, the loads transmitted to piles also increase, which places higher requirements on the work quality. One of the main requirements is the prohibition of deviation of the pile from the vertical beyond the limits established by the SNiP Norms. At the present time, control of the observance of this requirement is performed visually or with the help of the simplest plumbs. The device proposed in this article makes it possible to perform local and remote control of the verticality of the pile during the process of its installation and driving, by using a magnetic system and LED's (light-emitting diodes) to determine the position of a pendulum, which is the sensitive element of a primary detector.

Krichke, V.O. (Kuibyshev Civil Engineering Inst, USSR). *Soil Mech Found Eng* v 24 n 2 Mar-Apr 1987 p 61-62.

**078723 EXPERIENCE IN CHEMICAL STABILIZATION OF LOESS SOILS AT THE BASE OF BORED INJECTION PILES.** Injection piles of the type 'Mega,' 'Highway,' etc., are used widely in the construction of buildings and structures in Hungary, a characteristic of which is the placement in the pile body of a device for injecting a stabilizing reagent under its foot for creating a supporting mass of increasing bearing capacity. Such injection piles make it possible to increase its bearing capacity by simple methods and with small additional expenditures. The Scientific-Research Institute of Mechanics and Applied Mathematics of Rostov State University together with the Volgodonsk Administration of the State All-Union Trust for Stabilization of Foundations and Structures (Gidrospeitsstroj) has developed an original method of constructing a bored injection pile, the essence of which consists in chemical stabilization of the base under the pile foot with subsequent pressure testing of the stabilized mass with cement grout. 4 refs.

Badeev, S.Yu. (Rostov State Univ, USSR); Soshin, M.V.; Kuzin, B.N.; Isaev, B.N. *Soil Mech Found Eng* v 24 n 2 Mar-Apr 1987 p 72-75.

**078724 DRIVEABILITY OF PILES AND THE EFFECTS OF FOLLOWERS.** This paper presents a wave equation study on the effects of using pile followers on drivability and driving stresses, as well as drivability analyses of large-diameter offshore piles at three sites. The analyses were carried out using a new wave equation model. These show that the use of followers which are impedance-matched can result in minimal loss of drivability. The analysis also included followers for land piles driven below ground as may be required for piles supporting basements. For the drivability analyses, the drivability of large-diameter piles at three offshore sites was investigated. These cases were for piles driven in chalk, clay and sand. (Edited author abstract) 13 refs.

Wong, K.Y. (Natl Univ of Singapore, Singapore); Chow, Y.K.; Karunaratne, G.P.; Lee, S.L. *Geotech Eng* v 18 n 2 Dec 1987 p 167-184.

**078725 EFFECT OF VERTICAL LOAD ON FLEXURAL BEHAVIOUR OF PILES.** Analytical investigations suggest an increase in lateral deflection when a vertical pile is axially loaded, some published experimental investigations, both field tests and laboratory model tests, suggest a reduction in lateral deflection due to the presence of vertical load. The possible reasons for this contradiction are hypothesized. One reason is the reduc-

tion in tensile stress for axially loaded concrete sections. The restraint to the pile head imposed by the loading device used for the application of a vertical load is suspected to be another cause, and this is investigated in detail. For this purpose, a loading device was designed and fabricated which facilitated application of a vertical load without causing restraint to the pile head. Using the device, tests on fully and partially embedded model piles subjected to vertical and lateral loads were carried out. The results show that the presence of a vertical load causes an increase in lateral deflection, which is in agreement with the trend predicted by analytical methods. (Edited author abstract) 17 refs.

**078726 DRIVING AND TENSION LOADING OF PILES IN SAND ON A CENTRIFUGE.** A facility has been developed on the Cambridge 10 m Geotechnical Centrifuge to drive single piles into sand and then perform monotonic and cyclic tension load tests. The driving and loading are performed by two independent systems which have been optimised to meet the modelling requirement of each phase. Model open ended piles, instrumented externally along the length of the shaft, have been successfully installed and load tested using the facility. The paper describes the design of the model piles and details of the driving and loading equipment, and presents results from some of the pile tests. The resulting pile capacities and response under cyclic loading are discussed in the light of current design criteria for piles in sand. (Author abstract) 9 refs.

**078727 RATIONAL WAVE EQUATION MODEL FOR PILE-DRIVING ANALYSIS.** A one-dimensional wave equation model for pile-driving analysis is presented. In this model, the pile is represented by discrete elements, while the soil is represented by a series of springs and dashpots, the coefficients of which are derived using elasto-dynamic theory. The capability of the proposed model is demonstrated by comparison with field data of two instrumented piles. The analyses include predictions of set, and driving stresses at various levels of the piles. Comparisons are made with the sets and driving stresses predicted by the E.A.L. Smith model. From the analyses by the proposed model and load test results, estimations of soil setup for the two piles are also presented. (Edited author abstract) 30 refs.

**078728 PILE JETTING.** The state-of-the-art of pile jetting is reviewed. In general, jetting is a very effective time-saving method of pile driving. It can be effectively utilized for the driving of both vertical and batter piles. It is almost indispensable for the driving of wide flange piles, T-shaped sheet piles, or similar types of piling. The method requires very simple equipment, which typically includes a centrifugal pump, jet pipes, flexible pressure hoses, and a jet pipe handling winch. The flow rate and head required for the successful pile jetting primarily depend on foundation soil conditions and the type of pile. (Author abstract) 7 refs.

**078730 DYNAMICS OF PILE DRIVING BY THE FINITE ELEMENT METHOD.** It is proposed that the dynamics of pile driving based on the one-dimensional theory of wave propagation be analyzed by the finite element method. This approach enables one to continuously interpolate the displacement, velocity and acceleration profiles throughout the pile length. In contrast to the finite difference technique presented by E.A.L. Smith and the finite element procedure presented by I.M. Smith in which initial conditions are defined on the basis of a prescribed hammer velocity, the method presented herein defines initial conditions on the basis of a prescribed impact force versus time curve at the pile/hammer point of contact. Applications of the proposed technique to typical pile driving problems on an elastoplastic soil and using an implicit time-integration scheme are discussed using a numerical example. (Author abstract) 11 refs.

**078731 EXPERIMENTAL STUDY ON STRENGTH OF STEEL SHEET PILE MODELS UNDER REPETITIVE COMPRESSION.** This paper presents an experimental investigation on the buckling strength of stub channel columns under repetitive compression to determine cross sections of steel sheet piles against the repeated driving force by diesel hammer. The tests were performed under the pseudo-static condition using microcomputer-based servo-controlled testing system to find the deteriorating properties of steel sheet pile models undergoing the large elasto-plastic deformations under repetitive compression. Through the study, the deteriorating properties of the sheet pile model were clarified and found to be influenced by the width-thickness ratio, aspect ratio of the flange plates, and the relative dimensioning of the web and flanges. ## Earthquake Resistance

**078733 ANALYSIS OF LATERALLY LOADED PILES IN SOFT CLAYS.** The results of an alternative procedure to the p-y method for the elastoplastic analysis of laterally loaded piles are presented. This analysis is based on the boundary-element method and assumes knowledge of the shear-strength profile of the soil. In this paper, the shear strength is assumed to increase linearly with depth, a reasonable assumption for soft clays. The influence of soil yielding on the loading response of laterally loaded single piles is explicated by the results of a comprehensive parametric study. These results are cast in a form that is particularly suitable for design purposes. The validity of the analysis is demonstrated through comparisons with data obtained from a published case history. The ease with which the method can be applied to practice is illustrated by an example. (Author abstract) 15 refs.

## Elasticity

**078734 EFFECT OF NONLINEAR FLEXURAL RIGIDITY ON THE BEHAVIOR OF CONCRETE PILES UNDER LATERAL LOADING.** The flexural

behavior of a structural element such as a beam, column, or a pile subjected to bending is dependent on its flexural rigidity EI. The value of EI is found from the product of the modulus of elasticity of the material of which it is made and the moment of inertia of the cross section about the axis of bending. The value of EI is essentially constant for the level of loading to which a structural-steel member is subjected, but both E and I vary as the stress conditions change for a reinforced-concrete member. The EI value of a reinforced-concrete pile is assumed to be constant for simplicity in the analysis. This paper is concerned with the influence of variation of EI on pile behavior. The analysis of a field-loading test and some recommendations for design are presented. 5 refs.

## Friction

**078735 PILE SKIN FRICTION RELATED TO PARTICLE CHARACTERISTICS OF OFFSHORE CARBONATE SANDS.** This paper reports the results of tests on model pile shafts jacked into two types of carbonate sand. It is found that both particle size and particle grading characteristics influence the skin friction and soil modulus under static loading, and the degradation of skin friction under cyclic loading. (Author abstract) 7 refs.

Poulos, H.G. (Univ of Sydney, Aust); Lee, C.Y. *Res Rep Univ Sydney Sch Civ Min Eng* n R549 Aug 1987 31p.

**078736 EVALUATION OF GROUTED PILE FRICTION FROM GROUTED SECTION TESTS.** Data from grouted section tests at the North Rankin A site were analysed in order to determine parameters for static and cyclic axial response analyses of proposed insert piles in the underlying calcarenite layers. This paper describes briefly the method of interpretation of the data and the use of laboratory test data to try and reproduce theoretically the observed response. The development of cyclic degradation model is outlined. This model is then used in a boundary element analysis to investigate the behaviour of single inserts and groups of inserts under both static and cyclic loading. It is concluded that cyclic degradation of skin friction may cause a severe reduction of insert pile capacity and that insert piles of reasonable length may not have sufficient capacity to adequately support the maximum storm loads. However, many of the assumptions made in the analysis are conservative. (Edited author abstract) 11 refs.

## Performance

**078738 MONITORING THE BELOW GROUND PERFORMANCE OF LATERALLY LOADED PILES.** Lateral loading tests were carried out on an 'H'-section steel pile at a site near Plancoet, Brittany, to compare the information obtained from two instrumentation systems that were used to monitor the below ground performance of the pile. One of the systems used electrical resistance strain gages that were bonded to the pile and the other system used electro-levels (precise tilt indicators) that were installed in a tube that had been securely attached to the pile. Very good agreement was found in the bending moments, soil reactions and p-y curves determined from the two systems. Some of the factors that have to be considered when using each of the systems are briefly discussed together with their respective advantages and disadvantages. The approximate cost of the instrumentation used in the pile is given. (Author abstract) 7 refs.

Price, G. (Building Research Station, Watford, Engl); Wardle, I.F.; Frank, R.; Jezequel, J.F. *Ground Eng* v 20 n 5 Jul 1987 p 11-12, 14-15.

**078739 PERFORMANCE OF DRIVEN PILES IN A CRUSHED-ROCK-FILLED RECLAMATION.** With the increasing use in Hong Kong of crushed rock as a filling material in reclamations there was concern that this would create constraints to the selection of foundation methods for high rise housing estate developments. After the formation of a trial area of crushed rock reclamation, pile installations and tests were undertaken with pre-stressed concrete, steel H, steel tube and steel sheet piles. Machine-bored piles and a barrette were also installed, but this paper is limited to a description of the driven piles and the test results. All piles except the sheet piles were successfully installed although in some cases with difficulty. (Author abstract) 8 refs.

**078740 FINITE ELEMENT ANALYSIS OF MECHANISMS OF PILE GROUP BEHAVIOUR.** Solutions are presented for the non-linear load-settlement behavior of square-configuration pile groups. The groups are represented by an equivalent axially-symmetric model, and a nonlinear finite element is used to examine the mechanisms of group behavior and their variation with pile spacing. It is shown that, at close spacings, the block failure mechanism occurs, with significant plastic zones being developed below the group and full pile-soil slip only being developed along the outer piles. As the pile spacing increases, the failure mechanism gradually changes to the 'single-pile' mode, whereby full pile-soil slip occurs along all piles. (Edited author abstract) 9 refs.

## Service Life

**078742 LONG TERM BEHAVIOR OF PILES.** Longevity of structural units, as compared to the planned useful life of a facility, always is a design consideration. Typical concerns include slow-decay due to environmental factors, and changes in constitutive relationships

governing the performance of the material involved. With respect to foundations, the usual items of interest are corrosion of steel and concrete, and time dependent behavior of the soil/structure system. For piles, as with other foundations, deterioration is precluded, mitigated or otherwise accounted for by assessing properly the ambient situation (sulfates, pH, stray currents, resistivity) and providing safeguards, such as resistant construction products, oversizing, coatings, and/or cathodic protection. Long term performance of the pile foundations, as affected by time dependent characteristics of the pile foundations, as affected by time dependent characteristics of the supporting soil or rock, can be predicted and controlled only with a synergistic coupling of analyses and field tests. (Edited author abstract)

## Stability

**078743 CYCLIC STABILITY DIAGRAM FOR AXIALLY LOADED PILES.** This paper develops the idea of a cyclic stability diagram in which the mean and cyclic axial loads on a pile are plotted and three regions are identified: (1) a stable zone in which cyclic loading has no effect on pile capacity; (2) a metastable zone in which cyclic loading causes some limited reduction of load capacity; and (3) an unstable zone in which cyclic loading will result in failure of the pile within a specified number of cycles. An analysis that can be used to generate the stability diagram is described, and two examples are presented to demonstrate the characteristics of the three zones. One example also examines the relative importance of cyclic degradation and degradation due to a strain-softening shaft response. Finally, a comparison is made between theoretical predictions of the lower boundary of the unstable zone and the results of some field and laboratory tests. (Author abstract) 13 refs.

Poulos, H.G. (Univ of Sydney, Sydney, Aust). *J Geotech Eng* v 114 n 8 Aug 1988 p 877-895.

**078744 CYCLIC STABILITY DIAGRAM FOR AXIALLY LOADED PILES.** This paper develops the idea of a cyclic stability diagram in which the mean and cyclic axial loads on a pile are plotted and three regions are identified: a stable zone in which cyclic loading has no effect on pile capacity; a metastable zone in which cyclic loading causes some limited reduction of load capacity; an unstable zone in which cyclic loading will result in failure of the pile within a specified number of cycles. An analysis which can be used to generate the stability diagram is described and two examples are presented to demonstrate the characteristics of the three zones. One example also examines the relative importance of cyclic degradation and degradation due to a strain-softening shaft response. Finally, a comparison is made between theoretical predictions of the lower boundary of the unstable zone and the results of some field and laboratory tests. (Author abstract) 12 refs.

## Stresses

**078746 STRESS WAVES IN Laterally LOADED PILES.** The behavior of single vertical piles subjected to lateral loading at the pile head was analyzed. Based on the assumption of beam on elastic foundation, the analysis was made by using the method of direct analysis which is a numerical approach making direct use of governing physical laws without explicitly utilizing the differential equation of vibration. The analysis provides short-time pile response to pulse loadings. These results indicate, among others, that an interaction between the dilatation and shear waves results in a stress discontinuity of considerable magnitude which may deserve special attention in pile design. (Author abstract) 7 refs.

Wang, M.C. (Pennsylvania State Univ, University Park, PA, USA); Liao, W.P. *Int J Numer Anal Methods Geomech* v 11 n 6 Nov-Dec 1987 p 639-644.

**078747 ANALYSIS OF RESIDUAL STRESS EFFECTS IN PILES.** A simple method is outlined for analyzing the residual stresses in a single pile following driving or jacking, and for determining the subsequent axial load-deformation behavior. It is found that the stiffness of the pile head response is generally less for tensile loading than for compression loading. The most significant effects occur for piles in sand; piles in soft clay are not significantly influenced by the presence of residual stresses. The cyclic response of piles in sand may also be affected adversely by residual stresses. Comparisons with field and laboratory test data suggest that the theory incorporating residual stress effects can give reasonable estimates of axial pile behavior. (Author abstract) 12 refs.

## Structural Analysis

**078748 LOAD-DEFORMATION RESPONSE OF AXIALLY LOADED PILES.** A new empirical scheme for simulating the nonlinear point resistance response of single piles in cohesionless soils is proposed. The pile-soil system is idealized by using a one-dimensional finite element technique. The shear resistance response along the pile shaft is found by using the concept of  $t$ - $z$  curve proposed by L.M. Kraft et al., whereas the new method is used to define the tip resistance response or the so-called  $p$ - $z$  curve. A generalized Ramberg-Osgood model is utilized to simulate the nonlinear  $t$ - $z$  and  $p$ - $z$  curves. To check the validity of the method, four examples involving field and laboratory tests on piles in sands are considered. (Edited author abstract) 29 refs.

Armaleh, Sonia (Univ of Arizona, Tucson, AZ, USA); Desai, C.S. *J Geotech Eng* v 113 n 12 Dec 1987 p 1483-1500.

**078749 AXIAL AND LATERAL RESPONSE OF PILE GROUPS EMBEDDED IN NONHOMOGENEOUS SOILS.** A numerical method of analysis based on elasticity theory is presented for the analysis of axially and laterally loaded pile groups embedded in nonhomogeneous soils. The problem is decomposed into two systems, namely the group piles acted upon by external applied loads and pile-soil interaction forces, and a layered soil continuum acted upon by a system of pile-soil interaction forces at the imaginary positions of the piles. The group piles are discretized into discrete elements while the nonhomogeneous soil behavior is determined from an economically viable finite element procedure. The load-deformation relationship of the pile group system is then determined by considering the equilibrium of the pile-soil interaction forces, and the compatibility of the pile and soil displacements. The influence of soil nonlinearity can be studied by limiting the soil forces at the pile-soil interface, and redistributing the 'excess forces' by an 'initial stress' process popular in elasto-plastic finite element analysis. Additional study results are discussed. (Edited author abstract) 32 refs.

p 621-638.

**078750 INTERACTION BETWEEN TORSIONAL AND AXIAL PILE RESPONSES.** The effect of axial load on the torsional pile response and the effect of torque on the axial pile response are investigated. To perform this investigation, a computer program was developed which uses the transfer matrix method to analyze a pile supported by a series of coupled axial and torsional elasto-plastic springs. The study indicated that the ultimate torsional and axial pile capacities, as well as the axial displacements and rotations, are significantly affected by the combined load action. (Author abstract) 11 refs.

**078751 AXIAL INTERACTION BETWEEN DISSIMILAR PILES IN A GROUP.** This paper describes the results of an investigation into axial interaction among a group of dissimilar piles. Consideration is given to the settlement and load distribution in a group containing piles of different section or length, arranged in any general configuration, and subjected to static or cyclic axial loading. Solutions are presented for a circular eight pile group, for the following cases: (a) some piles in the group have belled bases (b) some piles have different lengths or diameters (c) some piles have reduced stiffness (to simulate construction defects). Under cyclic loading, it is found that degradation of skin friction begins at lower load levels in a group with dissimilar piles than in a group of identical piles. (Edited author abstract) 8 refs.

Poulos, H.G. (Univ of Sydney, Aust); Hewitt, C.M. *Res Rep Univ Sydney Sch Civ Min Eng n R512 Dec 1985* 30p.

**078752 LATERALLY LOADED PILES IN LAYERED SOIL.** Laterally loaded circular elastic piles in layered soil are analyzed by means of a rigorous elastic load transfer theory. In terms of effective stresses, the problem is decomposed into extended soil layers with elastic properties of the layered soil and a fictitious pile characterized by Young's modulus of the real pile and the respective Young's moduli of the soil layers. The unknown fictitious-pile shear force is determined from the condition that the horizontal displacement in the extended soil layers along the centroidal axis of the original pile location caused by a system of interactive forces is equal to the horizontal displacement in the fictitious pile. The real-pile shear force is obtained by combining the fictitious-pile shear force with the areal integral of the effective horizontal shear stress in the extended soil layers at the original pile position. Extensive parametric studies with regard to the maximum bending moment and pile top deflection are presented in graphical form for the design and analysis of laterally loaded piles in layered soil. (Edited author abstract) 15 refs.

**078753 TORSIONAL RESISTANCE OF SINGLE PILE IN LAYERED SOIL.** Lateral loads on an offshore structure may result in torsional moments acting on the individual piles. In the present work, simple mathematical solutions are developed for a torsionally loaded pile in a layered soil and nondimensional charts are presented for design purposes. 4 refs.

**078754 PREDICTION OF LOAD-CARRYING CAPACITY OF DRIVEN PILES.** Two methods are presented to estimate the load-carrying capacity of driven piles. These methods use a new wave equation model that incorporates the loss of energy to the soil mass through radiation damping of the soil. Conventional soil parameters are used in this new model. Both methods use the load-test result of a test pile to estimate the soil parameters at the site by set matching. These soil parameters are then used to predict the load-carrying capacity of similar piles

at the site in subsequent analyses from set measurements. The two methods are demonstrated by the prediction of the load-carrying capacity of 21 piles at four sites. (Author abstract) 28 refs.

Chow, Y.K. (Natl Univ of Singapore, Singapore); Karunaratne, G.P.; Wong, K.Y.; Lee, S.L. *Can Geotech J* v 25 n 1 Feb 1988 p 13-23.

**078755 TIME DOMAIN FLEXURAL RESPONSE OF DYNAMICALLY LOADED SINGLE PILES.** Adopting a Winkler assumption, a simple mechanical soil model is developed for the flexural response analysis of dynamically loaded piles. The model is defined by examining a frequency-domain analytical expression obtained for the dynamic response of a plane strain massless cylinder and an infinite medium system. Using this soil model, the time-domain transfer matrix is developed for the flexural response of a single pile. The steady-state harmonic response of a single pile is computed by both the present approach and a previously developed frequency-domain solution. Good agreement between the two computed results validates the present approach. The dynamic responses of single piles subjected to the lateral impulse load are computed for piles in both capability of the present approach. It is confirmed that the developed soil model and pile response formulation are very efficient in numerical computation. (Author abstract) 16 refs.

**078756 LATERAL LOAD ANALYSIS OF NON-LINEAR PILES.** The response of pile foundations to lateral loads depends on the interaction between the piles and the surrounding soil. Analysis of this response requires accurate characterization of the behavior of both the pile and the soil surrounding the pile. Commonly used existing methods for analysis of the lateral load response of single piles consider the nonlinearity of the soil resistance, but they treat the pile as a linear, elastic beam. The assumption of pile linearity may not be valid in many cases. This note introduces a method for representing nonlinear pile behavior in the analysis of laterally loaded piles. 7 refs.

**078757 DIMENSIONNEMENT DE PIEUX QUELQUES EXPERIENCES ET RECHERCHES EN GRECE.** [Design of Piles: Experiments and Research in Greece]. The author describes some experiments and research concerning the structural design of piles, the main purpose being to inform readers of current practice in Greece. He deals with the problem of factors affecting the behaviour of the pile and gives correlations between the modulus of elasticity of the soil on the one hand and the number of blows  $N$  (SPT) and the cone resistance (CPT) on the other hand, so as to be able to estimate the settlement of piles on the basis of the theory of H. Poulos and E. Davis. A brief description is also given of loading tests of tubes for predicting the bearing capacity and settlement of real piles. (Author abstract) 8 refs. In French.

**078758 ALLOWABLE COMPRESSIVE DESIGN STRESSES FOR PRESSURE-TREATED ROUND TIMBER FOUNDATION PILING.** Research at the University of Colorado on southern pine and Douglas-fir piling has determined that the existing building code design stress values of 1200 psi and 1250 psi, as deter-

mined by ASTM D-2899, are substantiated; but testing procedures should be revised. All full size piling tests should be standardized at 1/d ratios of 2:1, or confined tests performed. Also, it has been determined that theoretical design values for timber piling should not be based on the lumber criteria of D-245 and D-2555, but instead should follow the pattern set by engineers in the utility industry for timber poles, in accordance with ANSI O5.1. (Author abstract) 28 refs.

**078759 STEEL PILE LOAD TEST DATA.** The results of numerous pile load tests on high-capacity steel piles are presented. The test data were contributed by design firms and by members of the steelmaking industry or their consultants and represent actual field testing programs. Test results show that the safety factor which exists in many pile foundations is much larger than necessary. Therefore, more consideration should be given to designing pile foundations using load test results as a guide to provide economical yet safe structures. The ultimate capacities of the piles have been evaluated on the basis of interpretation of the load-settlement criteria stipulated by the representative codes. It is suggested that direct application of these data to sites with similar geological conditions be limited to preliminary design only. Final design parameters for any large project employing high-capacity piles must be substantiated by pile load tests and analytical interpretation. (Edited author abstract) 7 refs.

**078760 TEST ON MODEL PILE GROUPS IN CLAY.** This paper describes an investigation of the 2x2 model pile groups embedded in clay bed with floating pile cap subjected to vertical working loads. The experimental results were compared with elastic continuum analysis using homogeneous and non-homogeneous soil models. The comparisons suggest that the non-homogeneous soil model (the shear modulus varying linearly with depth) is more appropriate than the homogeneous model (modulus remains constant) for the clay bed. The elastic response of pile groups could be predicted on the basis of shear modulus evaluated from single pile load tests. (Author abstract) 5 refs.

**078761 ADFREEZING STRENGTH OF ICE TO MODEL PILES.** Results of tests to determine the adfreezing strength of freshwater ice to piles having different surface characteristics show that adfreezing strength increases with increase in the rate of displacement and loading of the pile. Surface coatings such as creosote on wood piles and paint and silicone sealer on metallic piles drastically decrease the adfreezing strength of ice. (Author abstract) 3 refs.

**078762 TEST PILING IN CRUSHED ROCK FILLING.** The article presents a report of an address to the Geotechnical Group of the Hong Kong Institution of Engineers on the title subject. It presents the results of pull-out tests of the piles carried out to estimate skin friction. The tests were carried out on steel H-piles and tubular piles. It was concluded that only a small value of skin friction was actually mobilized within the rock fill layer and the major portion of pull-out resistance was derived from the more cohesive alluvium and completely-weathered-rock layers.

Evans, G.L. *Hong Kong Eng* v 14 n 5 May 1986 p 21.

**078763 CYCLIC AXIAL DISPLACEMENT TESTS ON MODEL PILES IN CLAY.** Offshore structures

experience severe storm loading which is the most critical situation for foundation stability. Under these conditions considerable variations in axial pile forces occur and small cyclic axial displacements can develop, possibly resulting in a weakening of the adhesion bond between the pile and the clay soil. This article reports on investigations of these phenomena using small-scale physical modeling. Briefly the technique involves the study of a model pile element installed in a remolded clay bed. The pile models are elements in the sense that they are intended to represent a small part of a prototype pile at a particular depth, rather than the whole pile over its entire length. The surface of the bed can be surcharged so that any selected depth can be represented.

**078764 CYCLIC LATERAL LOADING OF A LARGE-SCALE PILE GROUP.** A large-scale group of nine steel-pipe piles in a closely-spaced arrangement was subjected to two-way, cyclic, lateral loading with water above the ground surface. The test was conducted in stiff, overconsolidated clay at a site in Houston, Texas. All of the piles in the group were extensively instrumented to allow the results to be compared with those from other piles in the group and from the testing of an isolated, single pile. The results emphasize the highly nonlinear nature of the pile-soil-pile interaction. A substantial reduction in ultimate soil resistance was measured in the group piles relative to that of a similarly loaded single pile for both the first cycle and for 100 cycles of load. (Author abstract) 10 refs.

**078766 FIELD MEASUREMENTS ON MODEL PILE IN TWO CLAY DEPOSITS.** The piezo-lateral stress (PLS) cell is an in situ testing device that is capable of providing simultaneous measurements of the total horizontal stress, the pore pressure, and the shear stress acting on cylindrical pile shafts during the various stages in the life of a pile. PLS cell measurements obtained during penetration and subsequent soil consolidation in two clay deposits are presented herein and clearly show that clay sensitivity has an important effect on pile shaft behavior. Moreover, measurements are in reasonable agreement with predictions based on the strain path method that are significantly different from predictions obtained by means of the more popular cavity expansion method. (Author abstract) 17 refs.

**078767 MODELLING LATERALLY LOADED PILES IN CALCAREOUS SAND.** A program of 17 model pile tests was performed on the Cambridge 10 m Geotechnical Centrifuge in order to investigate the lateral load performance of offshore piles in calcareous soil. The tests comprised monotonic and cyclic lateral loading of single piles and groups of two and three piles in reconstituted, uncemented calcareous soils from Bass Strait, Australia. The piles modeled prototype piles with diameters in the range 0.3 to 2.1 m. Each test had one instrumented pile with which bending moment distributions were measured. The paper describes the modeling techniques, the class of results obtained, the validation of model scaling factors and the application of the work. (Author abstract) 8 refs.

**078768 PILES IN CLAY UNDER CYCLIC AXIAL LOADING - FIELD TESTS AND COMPUTATIONAL MODELLING.** An extensive series of static and cyclic axial pile load tests have been carried out by the Norwegian Geotechnical Institute in an overconsolidated clay deposit. The test piles used were 5.15 m long with diameter of 15.3 cm. The cyclic capacity was determined in a load-controlled mode, and varied from 42% of the ultimate static capacity in symmetrical two-way loading to 76 to 100% in one-way cyclic loading. Large-displacement cyclic loading degraded the capacity further to about 30% of the static capacity. The static and cyclic interface skin friction are modeled well by direct simple shear tests on remolded reconsolidated clay when effective stresses at onset of loading are properly considered. General computational models for predicting the cyclic performance of piles must take into account both load and displacement controlled loading, and must satisfy compatibility in terms of both cyclic and average stresses and displacements. (Edited author abstract) 21 refs.

**078769 POSSIBILITY OF USING MULTISECTION COMPOSITE PILES OF SQUARE CROSS SECTION AND LONG LENGTH.** Composite piles have come into widespread use in connection with the expansion of construction into areas containing deep strata of weak soils, for example, in regions near the Baltic Sea. Composite reinforced-concrete piles of square cross section are normally used in industrial and civil construction. The trust 'Stroimekhanizatsii', Ministry of Construction of the Latvian SSR first experimented with their use in 1964, and at the present time, the volume of these piles has exceeded 180,000 m<sup>3</sup> in the Latvian SSR alone. Bolted, welded, and socket joints are used to connect the elements of the composite piles. With the trend toward an increase in the number of floors in buildings and the loads on the columns of industrial projects, the need has arisen to use composite piles of even greater length and with an even greater number of joints. To determine the feasibility of the use of these piles, the trust 'Stroimekhanizatsii' performed an experimental investigation under complex geological-engineering conditions. 3 refs.

**078770 PILE LOAD TESTS IN SALINE PERMAFROST AT CLYDE RIVER, NORTHWEST TERRITORIES.** At Clyde River on the northwest coast of Baffin Island, pile load tests were carried out in 1982. Three piles were subjected to loads of five different magnitudes for different durations. Creep settlement was initiated and persisted in all cases. Continuous curve fitting was carried out by computer, and the resulting smoothed strain rate plotted with time. The minimum settlement rates were compared with earlier predictions. They were generally somewhat faster than results from previous laboratory saline creep testing combined with theoretical pile design based on creep settlement. The tests highlight the dramatic reductions in foundation bearing capacity and acceleration in pile creep rates that can be expected in permafrost exhibiting significant pore water salinity. A simplified testing procedure suitable for laboratory or field testing is described. (Edited author abstract) 14 refs.

**078771 MEASURED AND PREDICTED AXIAL RESPONSE OF 98 PILES.** This article deals with the prediction of the response to monotonic axial loading of single piles in various soil conditions. A 98-pile load test data base was obtained from the Mississippi State High-

way Department and was used to evaluate 13 methods designed to predict the ultimate load of a pile and five methods designed to predict the settlement of a pile. The methods include SPT/ $S_u$  methods, cone penetrometer methods, a pressuremeter method, and a dynamic formula method. The accuracy and precision of each method is quantified statistically, and a risk analysis is performed in order to properly assess the factor of safety. A cost analysis is also performed in order to find the factor of safety that will minimize the cost of construction plus the cost of a potential failure. (Author abstract). 20 Refs.

**078772 DATA REPORT OF THREE DYNAMIC CENTRIFUGE MODEL TEST ON PILES AND PILE GROUPS.** This data report describes the centrifuge model test carried out (in April 1987) to study the earthquake response of piles and pile groups. Three tests were conducted; one with a single pile with a cap, one with a single pile without a pile cap and one with a group of four piles with a pile cap. The model construction and the experimental methods are described briefly. The data obtained in these tests are presented. In the geotechnical centrifuge modelling the prototype gravitational forces are simulated by centrifuge acceleration (N times the gravity). The earthquake accelerations are simulated by shaking the model flight with the acceleration N times higher than that of the prototype in order to satisfy the dynamic similarity. 4 Refs.

**078773 MOVEMENTS OF RIGID PILES UNDER ECCENTRIC AND INCLINED LOADS IN SAND AND CLAY.** The movement of single rigid soil vertical model piles and pile groups under eccentric, inclined as well as axial and horizontal loads are experimentally investigated. From displacements of single piles in sand and clay the vertical and horizontal secant moduli of soil are evaluated by relationships based on elastic theory. It is found that changes in the loading eccentricity cause induced anisotropy in sand. The values of secant moduli of sand and clay from pile tests are compared with the values obtained from laboratory plate bearing tests. Effects of grouping of piles on movements are analyzed by displacement and rotational ratios determined from tests. These ratios are compared with their experimental values given by Oda (1972). The method of pile installation and soil density are found to have significant influence on the displacement and rotation ratios from pile tests conducted in sand. (Edited author abstract). 12 Refs.

**078775 DYNAMIC BEHAVIOUR OF SINGLE PILES UNDER STRONG HARMONIC EXCITATION.** Dynamic experiments were conducted on large-scale model piles in sand subjected to strong horizontal and vertical excitation. The theoretical response curves are calculated using DYNA2 and PILAY2 computer codes, and using also for the vertical direction,

the theory of nonlinear vibration. The theoretical curves are compared with the experimental results. The dynamic behavior of the pile is presented as frequency response curves for displacement, stiffness, dashpot constants, and damping ratios. The influence of excitation intensity, repeated loading, and cap contact with soil on the dynamic behavior of single piles is investigated. (Author abstract). 23 Refs.

Han, Yingcai (Inst of Engineering Mechanics, Harbin, China); Novak, Milos. *Can Geotech J* v 25 n 3 Aug 1988 p 523-534.

**078776 EVALUATION OF PILE FRICTION FROM CONDUCTOR TESTS.** The paper considers the results of load tests performed on conductor pipes installed at North Rankin, with a view to evaluating the likely shaft capacity of the main driven piles. The average skin friction values measured from the conductor tests range from close to 20 kPa, down to as little as 4 kPa for a conductor that had been tested re-driven and then tested again. The low skin friction values are exacerbated by the slender nature of the conductor pipes and by the tensile direction of loading. Allowing for these factors, the average skin friction available to the main piles under monotonic loading is estimated as about 20 kPa. However, that value is liable to significant reduction under the action of cyclic loading. (Author abstract). 8 Refs.

Computer Aided Design

**078779 CIRCULAR PIPE-CONNECTIONS.** Designers sometimes need specially formed pipe bends to connect given openings. Choosing a curve of constant curvature for the central curve of such a pipe-connection improves its aerodynamical properties. Further pipe bends with circular central curve are much easier to produce than that based on arbitrary spatial curves. Hence the following geometric problem arises: Let (A, a), (B, b) be given line elements with skew oriented tangent lines a, b. How to connect these two elements by a smooth curve? How to fulfill additional requirements? Within the continuum of possible connections we pay attention only to the follow-

ing four cases: The connecting curve is a helix or it consists of two circles, of  $n \geq 2$  congruent circular arcs with congruent twist angles or of  $n \geq 3$  congruent circular arcs with almost congruent twist angles. Solutions of the first and third kind turn out to exist only if the given line elements are symmetric in a certain sense. We present an algorithm for generating curves of the fourth type with the aid of computers. (Author abstract) 3 refs.

Corrosion Protection

**078781 DES CANALISATIONS CONTRE LA CORROSION.** [Protection of Pipes Against Corrosion]. The rate of corrosion of iron and copper pipes was studied by investigating the gradient of the weight loss curve after 120 and 60 days for the iron corrosion studies. In the copper corrosion studies, the copper uptake after 10 weeks was taken as the magnitude of the copper corrosion. The paper shows that different pipe materials require different water qualities to minimize corrosions. On the basis of laboratory tests, field tests and observations from waterworks applying corrosion control methods, the following water composition seems to decrease corrosion in a distribution system of iron and copper pipes: pH 8-8.5; hydrogen carbonate 40-100 mg/ $\text{HCO}_3^-$ /l; calcium content 15-30 mg  $\text{Ca}^{2+}$ /l; sulphate and chloride as low as possible. 16 refs. **078782 THERMAL SHOCK OF A PIPE WITH A PARTLY CIRCUMFERENTIAL SURFACE CRACK.** Stress intensity factors are calculated at the deepest point of partly circumferential surface cracks in a pipe loaded thermally and by internal pressure. The method of calculation is based on weight functions using the program package 'EASY' developed by Mattheck and Munz. Numerical values of the stress intensity factors are given for various crack depths and crack lengths in a pipe with an inner radius to wall thickness ratio of 10. (Author abstract) 6 refs.

**078783 EFFECT OF AN AXIAL COMPRESSIVE LOAD ON THE STABILITY OF A CIRCUMFERENTIAL CRACK IN A STAINLESS STEEL PIPE THAT IS BUILT-IN AT BOTH ENDS.** Against the background of the integrity of boiling water reactor piping systems, this paper investigates the effect of an axial compressive load on the stability of a circumferential crack in a stainless steel pipe that is built-in at both ends. One end is fixed, while the other, though allowed to move in an axial direction, is subject to a transverse displacement, and crack instability is examined when this displacement is fixed. The circumferential instability of through-wall crack and the radial instability of a part-through and part-circumference crack are both examined. For both types of instability, it is shown that a compressive load has an adverse influence on crack stability only when the compressive load is a large fraction of the Euler critical load. (Edited author abstract)

**078784 TEARING OF CIRCUMFERENTIAL CRACKS IN PIPES LOADED BY BENDING.** The paper develops a theory of tearing for circumferential through-cracks in pipes. Resistance to tearing is postulated to be a consequence of invariance in shape at the tip of a growing crack. The present paper is concerned with the use of a crack growth hypothesis in place for a resistance curve to serve as an alternative theoretical foundation for stability analyses. **078785 INSTABILITY OF CIRCUMFERENTIAL CRACK GROWTH IN PIPES - III. A PIPE WITH BUILT-IN ENDS: THE EFFECTS OF (a) THE TYPE OF IMPOSED DEFORMATION, AND (b) THE FLEXIBILITY AT THE BUILT-IN ENDS.** This paper focuses on the instability of growth of a through-wall circumferential crack in a pipe that is built-in at both ends. Two issues are addressed: (a) the effect of the type of deformation (i.e. rotation and/or transverse displacement) imposed at some part of the system, and (b) the effect of the flexibility at the built-in ends. (Author abstract) 4 refs.

Smith, E. (UMIST, Manchester, Engl). *Int J Eng Sci* v 26 n 1 1988 p 95-102.

**078786 INSTABILITY OF CIRCUMFERENTIAL CRACK GROWTH IN PIPES - IV. THE EFFECT OF RESTRAINTS ON THE INSTABILITY CRITERION.** This paper examines the effect of a restraint imposed at some part of the system on the instability of growth of a through-wall circumferential crack in a straight-pipe that is built-in at one end, the pipe being subject to bending deformation due to a fixed displacement applied at the free-end. The results clearly demonstrate the beneficial effects of restraints on the stability of circumferential crack growth. (Author abstract) 6 refs.

## Cracking

**078787 FINITE ELEMENT ELASTIC-PLASTIC ANALYSIS OF GROWTH AND PENETRATION OF A SURFACE CRACK.** The authors have carried out a series of elastic-plastic analyses for circumferentially cracked pipes loaded in four-point bending. They have obtained load-displacement and the J-displacement curves and the crack opening area for cracks with various configurations. Based upon these curves, an engineering approach has been applied to estimate the stable growth and instability of a surface crack. The Battelle round robin on the crack growth has been estimated well by this analysis. (Edited author abstract). 5 Refs.

**078791 J-INTEGRAL ESTIMATION ANALYSIS FOR CIRCUMFERENTIAL THROUGHWALL CRACKED PIPES.** J-integral estimation solution is derived for pipes containing a circumferential throughwall crack. Bending moment and axial tension loadings are considered. These solutions are useful for calculating J from single load-displacement record obtained as part of pipe fracture testing, and are applicable for a wide range of flaw length to pipe circumference ratios. Results for J at initiation of crack growth generated using the solution developed in this paper agree well with J results from finite elements analyses. (Author abstract). 16 Refs.

## Deformation

**078792 PLASTIC DEFORMATION INDUCED BY PRESSURE TRANSIENTS IN FLUID-FILLED PIPES.** Severe pressure transients, caused for example by pump breakdown, may induce plastic deformation of a pipe wall. The speed of propagation of waves inducing plastic deformation is of importance in the analysis and design of piping systems. A general expression for the speed of propagation is derived. This also accounts for the type of pipe support. The analysis presented in this paper suggests that there is no propagation at the point of plastic instability. (Author abstract). 2 Refs.

Chohan, R.K. (Queen Mary Coll, London, Engl). *Int J Pressure Vessels Piping* v 33 n 5 1988 p 333-343.

## Equipment

**078793 SIZING THE ENDS OF PIPES AND PIPELINE PARTS.** The authors have developed a modified design of the sizing head. In this design the conical jaws have been turned by 180°. Therefore, the engagement between the jaws and the body is at the big end. This has resulted in a significant increase in the strength and reliability of the jaws and eliminated breakage when sizing thickwalled pipes. This device can be used for sizing pipes of diameter less than 108 mm (89, 76, 57 mm). The machine for sizing of pipes and pipeline parts of 57-325-mm diameter includes the sizing head, a hydraulic cylinder, a hydraulic power pack, an electric cabinet, and a control panel. Technical characteristics of the machine are presented. 1 ref.

## Failure

**078794 CAUSES FOR THE FAILURE OF WATER-HEATER PIPES IN AMMONIA PRODUCTION.** The causes for the failure of subassemblies and components of apparatus used for chemical production should be diagnosed using modern methods of investigation for the complex study of the properties of the damaged metal and the character of the fracture. The authors investigated the pipes of two water heaters that had operated for 11,163 and 1200 h, respectively. The pipes under investigation were compared with pipes formed from type 12Kh18N10T steel in the as-delivered state and after heating for expansion. 7 refs.

**078795 ANALYTICAL MODEL FOR FAILURE BENDING MOMENT OF STRAIGHT PIPES INCLUDING RESIDUAL STRESS AND OVALITY.** When a pipe breaks the fracture starts in the vicinity of an initial or nucleating defect, such a defect being usually located near to the weldment. In this paper, a four-parameter model is given which describes four fundamental aspects of the pipe section at the moment of breakage. These parameters are: (a) the effective stress in the uncracked area as defined by M.F. Kanninen, (b) the effective stress in the cracked area as defined by K. Hasegawa, and two new parameters to describe (c) residual stresses and (d) ovality. Additionally, a simplified approach to describe crack growth is included in the model. This approach requires two new parameters, namely the minimum defect length and the effective defect area at the failure instant. (Edited author abstract) 7 refs.

**078796 ESTIMATION OF THE DUCTILE UNSTABLE FRACTURE OF PIPE WITH A CIRCUMFERENTIAL SURFACE CRACK SUBJECTED TO BENDING.** Several simple limit-load criteria have been proposed to predict in a light water reactor (LWR) pressure boundary piping the failure bending moment of a tough pipe which has a circumferential crack and is subjected to an external bending moment. However, some of those limit-load criteria give an unconservative prediction when the pipe has a short and deep circumferential surface crack. The present paper proposes a semi-empirical limit-load criterion on the basis of test results. This limit-load criterion gives a conservative prediction by choosing the optimum parameter, even if the pipe has an arbitrary circumferential surface crack. The present paper also proposes a method to calculate the tearing modulus  $T_{appL}$  of the pipe containing the circumferential surface crack just after the ligament failure. Moreover, the

compliance of a four-point bending machine is converted to an equivalent pipe length, which is used to calculate the value of  $T_{appL}$ . (Author abstract) 13 refs.

**078798 RESEARCH ON THE COEFFICIENT OF RESISTANCE FOR PIPES WITH OBLATE CROSS-SECTIONS.** Based on theoretical analysis and experiments the friction factor and resistance coefficient for a tube and a tube bend of oblate cross-sections are determined. The main resistances are measured for a series of bends of oblate cross-sections with various angles. The regression equations and regression curves for resistance coefficients are presented. In general, the resistance coefficient for a series of bends is not equal to the sum of those of the bends. The experiments show that the ratio of the resistance coefficients ranges from 0.60 to 1.80. (Author abstract) 4 refs. In Chinese.

**078799 QUANTITATIVE DESCRIPTION OF THE THERMAL STATE OF THE SURFACE LAYERS OF A PIPE HEATED BY HIGH-FREQUENCY CURRENTS.** An attempt is made to establish the nature of the change in the temperature field accompanying heating of the external surface of a pipe with HFC. We examine two temperature states: continuous, as a result of which the temperature increases monotonically up to a maximum admissible value  $T_2$ , and impulsive, when the maximum temperature of the outer surface is reached very rapidly and is then maintained in the interval  $T_1 < T < T_2$ . To determine the temperature distribution, the heat-conduction problem is solved neglecting the composition and structure of the coating. It is concluded that impulsive heating with HFC is preferable for localizing a high temperature in the diffusion zone. The instantaneous value of the temperature at any point of the diffusion zone is the same and is practically equal to the temperature on the outer surface of the pipe at this time. 5 refs.

**High Pressure Effects**

**078800 CALCULATION OF CREEP STRESSES IN HIGH-PRESSURE PIPES.** The authors developed a program for calculation of residual creep stresses for pipes made of steel 30CrNiMo8 at any given moment of time of

their operation. To carry out the calculation, we analyzed the relaxation characteristics of this steel. A decrease of the stresses in the logarithmic time coordinate at different initial stresses of the specimens and test temperatures occurred the first 10 h according to a curve (unsteady regime) which later became an inclined straight line (Steady regime). The authors obtain the distribution of the creep-induced stresses with respect to the entire pipe wall, which, being summed with the operating stresses, leads to a redistribution of the stresses in the pipe during its operation. We have developed an algorithm and written a program for calculation (on an ES-1033 computer) of the stresses at any given moment of time from the beginning of operation of pipes made of steel 30CrNiMo8. We carried out calculations of the stressed state of specific pipes at different moments of operation under different operating conditions. 1 ref.

**078805 CERAMIC LAYER COMPOSITION OF METAL-CERAMIC COMPOSITE PIPES PRODUCED BY A CENTRIFUGAL-THERMIT PROCESS.** The ceramic layer produced by a centrifugal-thermit process consists of corundum ( $\alpha$ - $Al_2O_3$ ) and hercynite ( $FeO-Al_2O_3$  spinel) when inducing the thermit reaction with aluminum and iron oxide powders. Although the hercynite in the ceramic layer plays some role in improving mechanical properties of the ceramic layer such as toughness and thermal shock resistance, it is not desirable for improving the corrosion resistance because the  $FeO$  component included in hercynite would be attacked in highly acidic conditions. In the present work, in order to make clear the mechanism of  $FeO$  remaining in the ceramic products and to reduce its content, the centrifugal-thermit process was performed with  $Al$  and  $Fe_2O_3$  powder mixtures of the mole ratios ( $Fe_2O_3/2Al$ ) of 1.1, 1.0, and 0.9 under environments of nitrogen gas and air flow. It was also performed by adding  $Mg$  and  $Si$  powders to the stoichiometric mixture of  $Al$  and  $Fe_2O_3$  powders. (Edited author abstract) In Japanese. 7 refs.

**Mechanical Properties** See Also PIPE, STEEL—Manufacture; STEEL—Mechanical Properties.

**078807 ACCURACY OF DETERMINING THE STRENGTH PROPERTIES OF PIPE MATERIAL.** The result obtained by the methods of mathematical processing show that the value of the error in determining the strength properties depends strongly on the accuracy of determining the cross-sectional area of the specimens and on the accuracy of recording the load. When the requirements on the accuracy of measuring the specimens (up to 0.01 or 0.05 mm) specified by GOST 1497-84 and GOST 10006-80 are fulfilled, the error of determination of the strength characteristics in testing the cylindrical and segment specimens (longitudinal strips taken from pipes) varies up to 2% and that in the case of the specimens/nozzles up to 5%. In determining proof stress  $\sigma_{0.2}$  from the tensile diagram, the error increases and may vary additionally up to 3%. In determining the strength characteristics of the pipes on the basis of the nominal dimensions of the diameter and wall thickness, the error may reach 20%. The magnitude of the error rapidly increases with reduction of wall thickness. Therefore, the method of determining the strength properties of the pipes on the basis of the nominal dimensions may be recommended in cases in which the pipes are manufactured with high accuracy and if the ratio of wall thickness to diameter is, for example, not lower than 1.10. 3 refs.

## Oscillations

**078808 SELF-EXCITED OSCILLATION IN AN AXI-SYMMETRIC JET WITH A COAXIAL FINITE-LENGTH CIRCULAR PIPE.** An experimental investigation has been carried out on the sound resonance associated with the circular pipe of finite length, which is positioned coaxially downstream of a round free jet. Self-sustained oscillation arises due to the impingement of the free shear layer on the pipe's leading edge, and this results in the periodic production of discrete ring vortices in the jet. The predominant frequency of oscillation is found to vary intrinsically with the position of the pipe's leading edge as in the case of the circular ring, in which several modal stages of oscillation have been observed previously. However, when this intrinsic predominant frequency approaches the first or higher eigen-frequencies of the pipe, sound resonance between these two frequency components occurs. (Edited author abstract) In Japanese. 6 refs.

## Pressure Effects

**078809 PHENOMENON OF REROUNDING.** When the cross section of a circular pipe is loaded with external forces, e.g. ground forces and increased gas pressure, then a new shape will arise which of itself is in total equilibrium. This shape will only be correct if any part of it is also in equilibrium, i.e. the total of the moments of the external forces, e.g. at the end of the part, should be zero. With the computer program BPC3 this end state is obtained in three to four iterations. The end state created with the generally used formulas of Spangler is not obtained; nor is it obtained, even after ten iterations, with the computer program NASTRAN. (Edited author abstract) 5 refs.

## Production

**078811 PRODUCTION OF PIPES FROM BOROSILICATE GLASS.** Experimental evidence indicates that the most effective temperatures of the glass in the working chamber for the preparation of the vertical drawing machine and during the period of producing the pipes, and also such molding parameters as the drawing rate, the position of the cooler with the plate barrier screen, the diameter of the molding nozzle, the depth to which it should be immersed, and the value of the air pressure supplied to the pipe to be molded. During the launching and drawing of the pipe, the presence and distribution of the siliceous crust along the surface of the glass are important; this in turn affects the isothermia of the glass around the cooler. The drain provides for a constant renewal of the glass in the mechanized working chamber. These studies and the measures taken have made it possible to increase the molding rate of the 50-mm

borosilicate pipes by 35% (from 140 to 185-195 m/h) and of the 40-mm pipes by 60% (from 200 to 310-320 m/h). 1 ref.

## Stability

**078814 STABILITY ANALYSIS WITH LUMPED MASS AND FRICTION EFFECTS IN ELASTICALLY SUPPORTED PIPES CONVEYING FLUID.** This paper presents an accurate finite element procedure for the stability analysis of elastically supported pipes conveying fluid. With consideration of effects of lumped masses, fluid pressure and friction, the equations of motion are derived based on Hamilton's principle for the mass transport system. The kinematics of the pipe is based on Timoshenko beam theory for which the transverse shear deformation and rotary inertia of the pipe are included. The material behavior of the pipe is described by the Kelvin viscoelastic model. The dynamic stability behavior obtained by the present work are more conservative as compared with those evaluated by conventional Euler-Bernoulli beam theory. (Edited author abstract) 30 refs.

**078815 STUDIES ON THE STABILITY OF PIPES CONVEYING FLUID (THE EFFECT OF A DAMPER).** The intended aim of the paper is to provide the scope of the effect of an attached damper upon the stability of a cantilevered viscoelastic tubular pipe conveying fluid. The effect of the damage coefficient of a damper is investigated in detail in connection with the position of the damper as well. It is found that a damper attached to a thin pipe may have a little stabilizing effect on the pipe. Any damper attached to the pipe at the discharge end may be most destabilizing. A lumped mass accompanied by a damper may be destabilizing. The theoretical predictions were checked by some experiments. (Author abstract) In Japanese. 11 refs.

**078816 DYNAMIC STABILITY AND ACTIVE CONTROL OF CANTILEVERED PIPES CONVEYING FLUID (AN ATTEMPT OF STABILIZATION BY TENDON CONTROL METHOD).** Theoretical studies on the dynamic stability and active control of cantilevered pipes conveying fluid are conducted. In order to control the response of the cantilevered pipe, an active control force is derived by the torque produced by a pair of tendons attached to the pipe. The problem is solved by means of the Galerkin method, in conjunction with the optimal regulator theory. The effect of a tendon on the stability of a cantilevered pipe conveying fluid in the uncontrolled system is clarified. Furthermore, the effect of the internal damping is taken into consideration in the present study. The numerical simulation of the response of a cantilevered pipe conveying fluid is also carried out for various conditions. It is found that active tendon control method is effective to stabilize the cantilevered pipe conveying fluid, even if the control input is limited. (Author abstract) In Japanese. 14 refs.

**078817 STUDIES ON THE STABILITY OF PIPES CONVEYING FLUID (THE COMBINED EFFECT OF A SPRING SUPPORT AND A LUMPED MASS).** The present paper deals with the combined effect of a spring support and a lumped mass on the stability of a tubular cantilever conveying fluid. The support and the mass are assumed to be attached to the cantilever at the same location. The validity of Galerkin's 8 term approximation is discussed from the view point of predominant eigenmodes in critical flutter configurations. It is shown that for particular combinations of spring stiffness and lumped mass there exists an instability region which juts out from the main flutter domain. Both theory and experiment confirm that the instability in the region is of the mild flutter type, not the violent type. (Author abstract) 11 refs.

## Strain

**078818 OPTIMIZATION OF STRESS-STRAINED STATE OF THICK-WALLED TUBE ACCORDING TO MATERIAL ELASTICITY MODULUS.** The problem of finding the optimal distribution of the elastic modulus along the radius of a thick-walled tube subjected to an internal pressure is considered. Formulas are obtained for two cases: minimization of circumferential stresses and minimization of circumferential strains. Numerical results of the problem are presented. (Edited author abstract) 6 refs. In Russian.

**Stresses** See Also PIPE, CLAY—Physical Properties; PIPE, CONCRETE—Structural Analysis; PIPE, PLASTIC—Aging; PIPE, PLASTIC—Structural Design; PIPING SYSTEMS—Computer Aided Design; PRESSURE VESSELS—Stresses; TUBES—Calculations; TUBES—Strain.

**078819 FRICTION HEAD LOSSES IN PIPE.** Experiments have shown that the Darcy coefficient of friction  $f$  is not a constant but depends on the diameter of the pipe, quantity of flow, roughness of the pipe and the temperature. In the range of  $Re < 2000$ , the flow is laminar. The one with  $Re > 2500$  is turbulent flow. Based on the computations, laminar flow occurs when the Reynolds number is less than 2000 and turbulent flow occurs for larger than 2500. In between these values is called the transition period, or a mixture of both the

laminar and turbulent flow. Unfortunately, there is no equation or empirical formula governing it at the present time.

**078820 STRESS INTENSITY FACTORS FOR LONG AXIAL SURFACE CRACKS AT THE OUTER WALL OF A PIPE LOADED BY STRESS GRADIENTS.** By means of the finite element method, crack opening displacements were calculated for long axial surface cracks at the outer wall of a pipe. The wall thickness to inner radius ratio of the pipe was 1 to 10. Weight functions were evaluated by means of the finite element results. Using these weight functions it is possible to calculate stress intensity factors for arbitrary radially varying stress distributions. In this paper stress intensity factors were evaluated for a constant hoop stress loading as well as for stress distributions with a linear and a quadratic dependence on the radius. (Edited author abstract) 16 refs.

Grebner, H. *Materialwiss Werkstofftech* v 19 n 2 Feb 1988 p 51-54.

**078821 CALCULATION OF STRESS INTENSITY FACTORS FOR AXIAL SEMI-ELLIPTICAL SURFACE CRACKS IN A PIPE WITH CLADDING LOADED THERMALLY.** By means of the weight functions method the stress intensity factors were calculated for axial semi-elliptical surface cracks in a pipe with cladding. The component was loaded by a thermoshock. Starting from a stress-free state the inner surface of the cladding is suddenly cooled down. The time-dependent temperature and hoop stress distributions of the uncracked component were calculated. Numerical values of the stress intensity factors at the deepest point and at the surface points of the crack were evaluated at different time steps for a range of crack depths and crack lengths. (Author abstract) 8 refs.

Grebner, H. *Materialwiss Werkstofftech* v 19 n 1 Jan 1988 p 28-33.

## Supports

**078822 ROHRAUFLAGER NACH DIN 4033: 'JEDES ROHR BRAUCHT SEIN AUFLAGER.'** [Pipe Bedding According to DIN 4033: 'Every Pipe Needs Its Bedding']. The formation of the bedding for pipes is crucial to the uniform loading of the subsoil, it influences the amount of stresses and strains of the pipe, the settlements of the pipeline and is decisive for the watertightness of the pipe joints. The pipe bedding for sewers and sewage pipelines must be carried out according to the German standard DIN 4033 'Sewers and sewage pipelines, code of practice for construction'. The bedding should ensure uniform pressure distribution in the bedding zone. Pipes should therefore be laid in such a manner that there is neither line support nor point support. It is possible to lay pipes on a flat trench bottom if the bedding is produced by placing in layers and careful compaction of the bedding material. In German and English.

**Testing** See Also CONVEYORS—Pneumatic; PIPE, PLASTIC—Performance.

**078823 PIPE WHIP: A SUMMARY OF THE DAMAGE OBSERVED IN BNL PIPE-ON-PIPE IMPACT TESTS.** This paper describes examples of the damage resulting from the impact of a whipping pipe on a nearby pressurized pipe. The work is a by-product of a study of the motion of a whipping pipe. The tests were conducted with small-diameter pipes mounted in rigid supports and hence the results are not directly applicable to large-scale plant applications where flexible support mountings are employed. The results illustrate the influence of whipping pipe energy, impact position and support type on the damage sustained by the target pipe. (Edited author abstract) 3 refs.

## Transportation

**078824 HOW TO PREVENT TRANSIT FATIGUE TO TUBULAR GOODS.** Transit fatigue results from cyclic stresses induced by gravitational and inertial forces. The manner in which pipe is subjected to fatigue-inducing stresses during transportation is discussed. Transit fatigue is usually, but not always, accompanied by surface damage such as abrasion, denting and fretting. Surface damage can lower the fatigue resistance and, in the absence of denting, more cracks are found at the outside surface than at the inside. Based on a survey of failures, the data indicate that there appears to be no particular pattern of failures related to either the type of pipe, the grade or the mode of transport between rail and ship. Similarly, there appears to be no relationship between the number of failures and the size of pipe, although more have been expected in large diameter pipe or in pipe with larger diameter-to-thickness ratios. The characteristics of transit fatigue failures are outlined as are preventive practices. 5 Refs.

**Vibrations** See Also VIBRATIONS—Absorption.

**078825 TORSIONAL VIBRATION TRANSMISSIBILITY CHARACTERISTICS OF REINFORCED VISCOELASTIC FLEXIBLE PIPES.** The dynamic complex shear moduli of fiber and steel reinforced viscoelastic flexible pipes are determined by using a torsional non-resonance method. Material property master curves as a function of frequency and temperature are obtained by using reduced modulus methods. In situations where the loss factor data is difficult to measure directly it is shown that these data can be obtained from the modulus data by using a stepwise Hilbert transform technique. Predictions of the torsional vibration transmissibility of reinforced pipes, by using a simple theory in conjunction with the material properties, results in a close comparison with experimental measurements of the torsional vibration transmissibility characteristics of the pipes over a wide frequency range. (Author abstract) 19 refs.

## Wear

**078826 PIPE BEND WEAR - IS TUNGSTEN CARBIDE THE ANSWER?** The article compares relative wear resistance of various grades of sintered tungsten carbide liners against a mild steel standard in a full pneumatic conveying test rig. Specimens ranging in cobalt content from 6 to 30 per cent and in grain size from 0.56 to 2.98 microns, including a mild steel standard, were placed on a specially designed holder which fitted into a tee type 100 mm diameter bend. The specimens were tested under various operating conditions, i.e. air velocity ranging from 28 m/s to 52 m/s, impact angles of 30° to 70°, mass flow rates of 35 kg/min to 83 kg/min and phase densities of 1.2 to 2.9, using a 4 mm nominal size crushed granite rock. The experimental results show that the ultrafine-grained, low cobalt (6 per cent) tungsten carbide displays little sensitivity to varying velocities, impact angles, mass flow rates or phase densities, and consistently gave the best wear resistance under all testing conditions. An empirical model for the prediction of wear for each type of material tested has been proposed, given the particular operating conditions. (Edited author abstract) 12 refs.

## PIPE, CAST IRON

### Corrosion Protection

**078834 PROTECTION OF DUCTILE IRON PIPE AGAINST CORROSION.** Cast iron pipe has a long history in Japan of approximately one century since it was used for the first time in Yokohama city in 1885. It has been widely used as an excellent pipe with high durability. In this description, the results of a survey and investigation on corrosion of the external and internal surfaces of cast iron pipe, and also about the corrosion protection methods, are summed up. A statistical analysis of the data resulted in a clear correlation between corrosion rate and soil characteristics (existence of underground water, Redox potential, soil color, soil resistivity, etc.). As an external protection procedure, tar-epoxy or bituminous coating is generally used. Also, zinc rich paint coating or zinc spray specified in ISO standards can be applied as a prior coating. However, when laid in the much higher corrosive areas, very high corrosion resistance is required. In such cases polyethylene sleeving method, polyurethane coating or polyethylene coating is adopted.

### Quality Control

**078836 QUALITY CONTROL TEST FOR CAST IRON PIPES USING ACOUSTIC EMISSION.** Cast iron water pipes are currently produced in conformity with GOST [All-Union State Standard] 9583-75 and TU14-3-259-77. The existing specifications are based on a maximum working pressure of 1.6 MPa. The producers test the pipes at 2.5 times the maximum working pressure, i.e., at 2.5-4 MPa depending on the class and diameter of the pipes. When pipes are tested in a hydraulic press, they are not merely subjected to an internal pressure which must be withstood with a wide safety margin [1]; they are also subjected to longitudinal bending, since the pressure force on the pipe ends amounts to 900 kN. These testing conditions often result in pipe failure under what is intended only as a soundness control check. 3 refs.

### PIPE, CLAY

#### Contamination

**078837 PROBLEM OF NaCl-CONTAMINATION IN VITRIFIED-CLAY PIPE (VCP) BODIES.** Depending on how the vitrified-clay body is pretreated and dried (in room air, in a tunnel dryer, or in a chamber dryer), wet-glazed VCP shows various surface defects. The main cause of defect is the nature of the NaCl-concentration profile, with the highest concentration occurring at the body/glaze interface. The concentration profiles are plotted, and the reaction mechanisms are interpreted. (In German and English)

**Manufacture** See Also CERAMIC PRODUCTS—Manufacture; CLAY PRODUCTS—Manufacture.

**078838 SINGLE-COURSE JET DRYING AND FIRING OF CERAMIC PIPES IN FURNACES WITH A GAS CUSHION.** Attempts were made to create new heating equipment for which the operations of placing the greenware on tunnel drier and kiln cars is not needed. One such unit could be that using single-course, jet drying-firing of ceramic drain pipes in special, perforated, semicylindrical trays, and transfer on a gas cushion. The advantages of the continuous, single-high method of drying and firing are as follows: elimination of cars, the possibility of creating mechanized and automated drying and firing processes, improvements in the uniformity of the temperature field in the goods, and a marked reduction in the heat-process time (drying and firing), a reduction in the number of personnel servicing the plant, and improvements in working conditions. 2 refs.

### Physical Properties

**078839 NEW BEDDING FACTORS FOR VITRIFIED CLAY SEWER PIPES.** New bedding factors were predicted by the finite element analyses of buried vitrified clay pipes with four types of backfill and bedding materials. These bedding factors were calculated as the ratio of the maximum tensile strain in the computer-simulated three-edge bearing test of vitrified clay pipes to that in the finite element analyses of buried pipes. The new bedding factors are generally higher than those given in the current ASTM specifications. It is shown that the bedding factors are affected by the backfill material type and compaction density, backfill height, trench width, and

pipe diameter. Design practice around the world is also summarized. (Edited author abstract). 21 Refs.

**Manufacture** See Also WATER PIPELINES.

**078840 IT'S THE HANDLING THAT COUNTS - SIMPLE IN-PLANT HANDLING SYSTEMS FOR FRESH AND HARDENED CONCRETE PIPES AND MANHOLE SEGMENTS.** Fully automated as well as simple systems are available for handling fresh and hardened concrete pipes and manhole segments. In this report, simple systems for a variety of handling tasks are described. Simple systems, for the purpose of this report, are ancillary devices that can be attached to fork lifts or cranes. The handling tasks have been divided into pipes and manhole segments; essentially, they consist of a sensible means of transport from the production site to the curing station; and from there to storage and truck. (Edited author abstract) In German and English.

Kroemer, Rupert. *Betonwerk Fertigteil Tech* v 53 n 9 Sep 1987 p 643-652.

**078841 PIPEMAKER'S CONFIDENT STAKE IN THE FUTURE.** The purchase of one of the latest models of Prinzing pipemaking machinery underlines a faith in the future by Jphohnston Pipes Ltd. Now, while retaining the traditional expertise garnered over 50 years, as one of the UK's surviving half-dozen major pipe manufacturers, Johnston Pipes are fully committed to the use of vertical casting with high frequency vibration. This is by no means a new method of manufacture.

Barfoot, Jack (Johnston Pipes Ltd). *Concrete (London)* v 22 n 1 Jan 1988 p 29-31.

**078842 PRECAST CONCRETE PIPES COPE WITH THRUST-BORE SITE PROBLEMS.** Good progress is reported from the £4.4 million Ashcroft Road to Parr Treatment Works sewer replacement scheme in St Helens, Lancs. In their choice of tunneling methods the designers selected thrust boring in preference to using bolted segments, to minimise the number of joints and so avoid the possibility of ground water inflows carrying chemical elements into the sewer and through to the treatment works. Thrust-bore quality precast concrete pipes with high-grade joints were adopted.

Anon. *Concr Plant Prod* v 6 n 2 Feb 1988 p 55-56.

**078843 CHANCEN UND HERAUSFORDERUNGEN DER BETONROHRHERSTELLER.** [Chances and Challenges of the Reinforced Concrete Pipe Producers for the Future.]. The sociopolitical significance of wastewater removal increases with rising awareness of the environment. Concrete can continue to be the market leader. Prerequisites are: Furtherance of the quality consciousness of employers; compilation of quality standards; conductance of quality controls; and marketing of pipes with a quality seal. (Author abstract) In German, English.

Kroemer, Rupert. *Betonwerk Fertigteil Tech* v 54 n 7 Jun 1988 p 26-27.

**078844 AUTOMATION IM QUALITÄTSORIENTIERTEN PRODUKTIONSABLAUF VON ROHREN AM BEISPIEL DES ROHRWERKES RISSE, WARSTEIN.** [Automation in Quality-Oriented Pipe Production on the Example of the Risse Pipe Factory, Warstein.]. The quality thought in production flows is related to the production stages concrete preparation, the actual manufacturing process including - in the

case of reinforced concrete pipes - reinforcing cages, in-plant handling of the fresh and finished products, bottom pallet circulation, and quality control. Only the optimization of these individual stations and their finely tuned interplay enables quality-oriented production flow. The Steinwerke F.J. Risse, D-4788 Warstein, have found their solution to this problem based on their particular requirements. Their product line includes concrete and reinforced concrete pipes of DN 300-2000 mm and individual manholes and accessories. This paper describes the automated pipe production manufacturing process. In German and English.

Kromer, Rupert. *Betonwerk Fertigteil Tech* v 54 n 7 Jun 1988 p 46-51.

**078845 VOLLAUTOMATISCHE FLEXIBLE ROHRFERTIGUNG MIT INTEGRIERTER ZWEIFACHER QUALITÄTSPRÜFUNG.** [European Market Firmly in Sight. Fully Automatic Flexible Pipe Production with Integrated Double Quality Assurance]. Nijmeegse Betonindustrie De Hamer bv - a company of the R.W.K.-Group - produces in its four concrete and assembly unit works a complete range of products for public works, road and bridge construction and hydraulic engineering. Recently, the company's management have been working on the design for a new production plant for manufacturing concrete and reinforced concrete pipes, which became fully operational at the beginning of this year in Nijmegen. The remarkable features of this plant are its almost completely automated mode of operation, a high degree of versatility and assured pipe quality as a result of integrated inspection equipment, as this report confirms. (Edited author abstract) In German, English.

Schwarz, Siegfried. *Betonwerk Fertigteil Tech* v 54 n 7 Jun 1988 p 52-58, 60.

## Quality Control

**078846 COMPARISON OF THE QUALITY CONTROL OF REINFORCED CONCRETE PIPES ACCORDING TO DIN 4035, ASTM C 76 AND BS 5911 TAKING THE BEARING CAPACITY AS AN EXAMPLE.** There is a close connection between the standardized construction and design regulations for reinforced concrete pipes and the applicable stipulations regarding quality control. The wider the scope of pipe construction, the more precisely adherence to the stipulated qualities must be supervised and controlled. The basic differences can be clearly illustrated based on the three standards, the American ASTM C 76, the British BS 5911 and the German DIN 4035. Each of these three alternatives has its own particular advantages. In German and English. 6 refs.

Hornung, Karl. *Betonwerk Fertigteil Tech* v 53 n 9 Sep 1987 p 616-620.

## Reliability

**078847 DAUERHAFTES ROHRLEITUNGEN AUS BETON.** [Durable Piping Made of Concrete]. Water and sewage pipes were made of Roman concrete as long as 2000 years ago. In our day and age concrete is also an excellent material for applications involving water and sewage - thanks to its pressure and abrasion resistance, its long service life and its practically unlimited moldability. The article treats the durability of concrete, with special emphasis on chemical corrosion. (Author abstract) In German. 17 refs.

Lamprecht, Heinz-Otto. *Beton* v 37 n 11 Nov 1987 P 437-442.

## Structural Analysis

**078848 PERFORMANCE OF THIN-WALL CONCRETE PIPE.** An analytical and experimental study was conducted of thin-wall unreinforced-concrete pipes of dimension ratios 16 through 70 under surcharge loads equivalent to 30 ft of fill. Special attention was directed

towards bedding and trench properties and geometries. The advantages and efficiencies of matching the stiffnesses of the bedding with that of the soil envelope are discussed. Narrow trench widths are shown to be more efficient when trench fill is of lesser stiffness than trench walls. Recommendations for practice are made. (Author abstract). 8 Refs.

## PIPE, COPPER

### Corrosion

**078849 CORROSION EXTERIOR DE TUBERIAS EN LA VIVIENDA. III PARTE. TUBERIAS DE COBRE.** [External Corrosion of Pipes in Housing. III. Copper Pipes]. An attempt was made to evaluate the corrosion process of copper tubing in contact with both low cement/sand ratio Portland mortars and plaster. Tests were carried out for one year in conditions of partial immersion in distilled water and also in environments with 50 and 100 percent relative humidity. An attempt was made to distinguish the effects due to the carbonation of the mortar as well as those of the  $\text{CaCl}_2$  addition to the mixing water in corrosion phenomena. Electrochemical techniques using both direct and alternating current, were used for the corrosion process evaluation. Results obtained showed that the corrosion of copper is normally lower than that suffered by the other metallic materials tested: steel and galvanized steel, considered in Parts I and 2. Nevertheless, an apparent anomaly was observed in the case of plaster in 50 percent relative humidity, in which case  $\text{Cu}_2\text{O}$  was formed. (Edited author abstract). 22 Refs. In Spanish.

Huete, F.A. (Centro Nacional de Investigaciones Metalúrgicas, Madrid, Spain); Royuela, J.J. *Rev Metal (Madrid)* v 24 n 2 Mar-Apr 1988 p 67-76.

**078850 CORROSION AND ITS PROTECTION OF EVAPORATOR'S RED COPPER HEATING PIPE IN CHEMICAL PRODUCTION OF SALT.** This paper makes comparisons between red copper and carbon steel heating pipes. These heating pipes are used in the salt industry, where they come in contact with ocean bittern, well brine, or lake and mineral brine. These brines consist of  $\text{Cl}^-$ ,  $\text{Na}^+$ ,  $\text{Mg}^{++}$ ,  $\text{Ca}^{++}$ , and  $\text{SO}_4^{--}$  along with harmful gases. These gases cause corrosion of the equipment and seriously damage heating pipes. It has been shown that red copper pipes are better than carbon steel.

Ma, Xinhua (Inst of Light Industry, Tianjin, China). *Key Eng Mat* v 20-28 pt 1-4 1988, 10th Int Congr on Met Corros, Madras, India, Nov 7-11 1987 pt 1, p 753-755.

**078851 FAILURE OF COPPER PIPES IN KUWAIT'S DOMESTIC TAP WATER.** Annealed phosphorus deoxidized copper water pipes which failed after 16 and 20 months of service in hot and cold water piping, respectively, were investigated. When the pipes were sectioned, some areas were covered by bluish-green crusts and the rest by a dark-greyish layer. Pits were found along a longitudinal axis. The pits were hemispherical in shape, and intergranular corrosion was observed inside and around the pits. Residual carbon found on the internal surfaces of the pipes varied from 1.2 to 4.7 mg/dm<sup>2</sup>. The water contains high levels of chloride, sulfate, and a lower level of bicarbonate. The pH ranges from 7 to 9, and the water was treated with a silicate-phosphate inhibitor. (Edited author abstract) 18 refs.

## Analysis

**078852 COLLAPSE CHARACTERISTICS OF A THIN-WALLED ELBOW: VALIDATION OF AN ANALYTICAL PROCEDURE.** A nonlinear analysis procedure is validated in this paper to predict deformation response, up to collapse, of thin-walled Liquid Metal Reactor (LMR) piping elbows. Nonlinear shell analysis predictions are compared with experimental measurements of two full-scale large diameter (406 mm), thin-walled ( $D/t = 38$ ), piping elbows tested at room temperature and at an elevated temperature in the Multi-Load Test Facility (MLTF) at Westinghouse. The overall and local deformation predictions agree very well with the measured deformation responses up to 60 percent of the measured plastic collapse moment,  $M_{pc}$ . The analytical-experimental correlation is reasonable up to 0.8  $M_{pc}$ . At higher load levels the correlation is not as good; at collapse the analysis overpredicts measured deformations by as much as 30 percent. (Author abstract) 16 refs.

## Cutting

**078853 DEVICE FOR GAS CUTTING OF FITTINGS ALONG THE LINE OF CONTACT WITH EQUIPMENT CASINGS.** The authors have developed a special device for mechanized gas cutting, without preliminary marking, of tubular fittings which are to be mounted along the central axes of different equipment, or along the line of contact with the casings of equipment. The device can be mounted on standard welding positioners or rotary rigs which can ensure rotation of the fitting at the speeds necessary for gas cutting and which have a smooth regulation of faceplate speed. The device consists of welding positioner and a gas-cutting device. The device comprises of a cross-type faceplate used for centering the fitting; a special column for mounting the gas torch; and a shaft with interchangeable cam. Actual use of the device under production conditions showed that reliability was high, resetting was fast, and servicing was simple. 1 ref.

## Hydrodynamics

**078854 INVESTIGATION OF HYDRODYNAMICS OF TWO-PHASE FLOW IN A TEE.** Two-phase flows in pipelines of power-generating plants are often split into different branches. The physical pattern of the process is sometimes complicated by the fact that, after splitting, one part of the flow is underpressure and in the other steam bubbles through a layer of water. The authors present the results of an experimental investigation of hydrodynamics of steam-water flow in a tee of equal passage areas, formed by a vertical tube with a horizontal branch. In the bottom vertical branch and the horizontal branch the flow is under pressure and in the top vertical branch steam bubbles through a layer of water with a free level. The investigation was conducted on an experimental apparatus, the main element of which is a high-pressure vessel with vertical tee fitted in it. 3 refs.

Stresses

**078855 STRESS AND STRENGTH ANALYSIS OF CONCENTRIC REDUCERS CONSISTING OF PLATES.** This paper presents a new kind of piping component - a concentric reducer consisting of plates. The authors performed experimental and elastic, elastic-plastic analyses on five test models having different structural parameters. The elastic stress distribution under hydraulic test pressure, the extension of the plastic region under higher than operating loads and the results of bursting tests are also reported on. Results indicate that under test pressure the maximum stress occurs at the inside of the junction area between the small end of the reducer and the small end of the tube. Yield and final burst also occur at this area under higher than operating pressure. Based on the results of the analysis, it can be concluded that the reducer is safe and reliable. (Author abstract) 6 refs.

**078856 DISPLACEMENT-BASED PIPE ELBOW ELEMENT.** A new element for stress analysis of piping is presented. The element can handle interaction effects and can be seen as an enhancement of the element from K.J. Bathe and C.A. Almeida. The necessary inter-element continuity for the elbow skin is assured through Hermitian interpolation of the ovalization pattern in the axial direction. The inclusion of warping for the elbow cross-section increases the element's capability. The main characteristics of the C<sup>0</sup> elbow element, the easy handling of boundary conditions and the satisfaction of the rigid-body mode criterion, are retained. (Author abstract) 7 refs.

Structural Design

**078857 STRESS INDEX METHOD OF DESIGN: APPLICATION TO IN-PLAND CLOSING COLLAPSE OF ELBOWS.** This paper presents an appraisal of the design rules for bends under primary moments. For the study, we have examined over 70 experimental results, half of which concern closure bend tests. We find that the current design rules for level D loadings offered by the codes are unsafe for large angle ( $\geq 60^\circ$ ) or low pressurized pipe bends, so we propose a new formulation for a more suitable B<sub>2</sub> index, founded on the limit analysis carried out by Spence and Findlay, and on empirical corrections based on our experimental results. The paper provides advice on the use of ASME limits applicable to all components. (Author abstract). 11 Refs.

Surfaces See JOINTS—Stresses.

Testing

**078858 EXPERIMENTAL STUDY OF BEHAVIOUR AND FUNCTIONAL CAPABILITY OF FERRITIC STEEL ELBOWS AND AUSTENITIC STAINLESS STEEL THIN-WALLED ELBOWS.** This paper presents the results of two series of tests performed on 90°C large-radius elbows. A first series of 10 tests was conducted on TU 42 C (equivalent to ASME SA 106 grade B) ferritic steel elbows with an outside diameter-to-wall thickness ratio of 6.7. A second series of 15 tests was conducted on Z2 CN 18-10 (equivalent to ASME TP 304 L) austenitic stainless steel elbows with an outside diameter-to-wall thickness ratio of 90. The test supplied extensive data on the behavior of thin-walled austenitic stainless steel elbows when subjected to large displacements, including ability of the elbow to carry the flow under high loadings. Analysis in accordance with the requirements of the RCC-M was also performed to

quantify flow area reduction at stress limits allowed by these rules, in addition to the displacement amplitude margin allowed by the level D service limit criteria with respect to the experimental limit moment. (Edited author abstract). 4 Refs.

Thermal Effects

**078859 SELECTION OF BOUNDARY CONDITIONS IN PERFORMING THERMAL CALCULATION OF PIPE FITTINGS.** For thermal calculations of fittings by numerical methods on a computer, boundary conditions of the third kind are specified, whose basic parameters are the temperature of the process medium  $t_m$ , the rate  $b$  of change of the process medium temperature, and the heat exchange coefficient  $\alpha$ . In this paper, the authors attempted to determine the degree to which the rate in change of the medium temperature affected the temperature field of the flange connection of the fitting. For this purpose the authors used the numerical method of finite differences and experimental investigation of a mode of a shut-off valve. 3 refs.

**078860 RELIABILITY OF MECHANICAL WRENCHES FOR SCREWING TOGETHER AND UNSCREWING PUMP AND COMPRESSOR PIPES.** In the investigation of the actual values of the parameters of the automatic machine APR-2VB we studied the processes of screwing together and unscrewing PCP (pump and compressor pipes) with nominal diameter 60, 73, and 89 mm. It was established that the maximal torques provided by the automatic machine APR-2VB (with two fly-wheels) in screwing together and unscrewing pipes are the following: from the place without withdrawal of the driving pinion from the handle of the wrench 550 N·m; with withdrawal of the driving pinion from the handle of the wrench through an angle of up to  $360^\circ$  with one impact of the driving pinion 870 and 890 N·m, respectively; with withdrawal of the driving pinion from the handle of the wrench by an angle of up to  $360^\circ$  and several (5-6) impacts of the driving pinion 1410 and 2250 N·m, respectively. Processing the results of the experimental data on the screwing together and the unscrewing of PCP with the use of the least squares method yielded the regression equations presented. The mathematical model of the dependence of the probability density of breakdowns on the number of worked cycles of screwing-unscrewing for insert pieces of wrenches KTDU is presented. 2 refs.

**078861 PHILADELPHIA PUTS PYPLOK TO SLEP TEST.** The Philadelphia Naval Shipyard is getting better and better at extending the life of elderly aircraft carriers under the Navy's SLEP (Service Life Extension Program). The USS Kitty Hawk is the fourth one in the yard, following the Saratoga, Forrestal, and Independence. New technology being used on the Kitty Hawk should prove more successful. In the pipe shop a change in the way that pressure piping is being permanently connected in some areas of the ship is showing very satisfactory results. This article reviews a new recently approved technology: Pyplok swage marine fittings, manufactured by Deutsch Metal Components, Gardena, Calif. Pyplok high-pressure, 6,000 lb/in<sup>2</sup> fittings have been authorized by NavSea as a method of joining piping systems on specific classes of non-nuclear surface ship since 1980, and 3,750 lb/in<sup>2</sup> stainless steel fittings received approval for a limited number of systems in 1983.

Analysis

**078862 FINITE ELEMENT SIMULATION OF JUMP-OUT BEHAVIOR OF THREADED PIPE JOINTS USED IN OIL-PRODUCING WELLS.** High tensile strength is one of the most important requirements for threaded pipe joints used in oil or gas-producing wells. If an excessively large tensile load is applied to the joints, a jump-out phenomenon of the pipe from the coupling occurs. The jump-out phenomenon depends largely on the thread profile, the nonlinear material properties and the contact condition at threads. In this paper, as a fundamental study, the jump-out behavior of a one-ring thread model was experimentally investigated and the FEM simulation was conducted considering the material nonlinearity and the contact condition at threads. Here, the penalty function method was applied as a technique of introducing contact condition into a large deformation elasto-plastic FEM code CAPS, which has been developed by the authors. **078863 ACCURATE SIMPLE MODEL TO EVALUATE INTEGRAL FLANGE ROTATION.** Bolted flanged joints must satisfy the requirements of structural integrity and be leakproof. To attain the latter goal we need accurate information from the gasket and the flange ring rotation. In this work an approximate formula to evaluate the flange rotation is presented. To obtain it, a model which behaves in an equivalent manner to the Murray and Stuart model is proposed. Several flanges distributed over the proposed domain are computed. Satisfactory ring rotation results are obtained. (Author abstract) 5 refs.

**078866 DETERMINATION OF THE INITIAL GAPS BETWEEN FLAT FLANGES WITHOUT GASKETS.** This paper describes a method of finding the size and shape of the gaps which exist between the faces of an assembled but unloaded flat-faced, metal-to-metal flange joint. The low-pressure leakage of 26 such assemblies has been measured experimentally, and pressure tappings have been used to record the pressure distribution under the contact faces of some of the flanges. Formulae are derived for the conversion from experimental data to gap size and shape. The method gives a very sensitive measure of gap height because of the cubic nature of the conversion formulae. It is shown by finite element calculations that

deflections due to bolt loading of a perfectly flat flange are much smaller than the observed initial gaps. (Edited author abstract) 6 refs.

Lewis, L.V. (Univ of Nottingham, Engl); Fessler, H.; Hyde, T.H. *Proc Inst Mech Eng Part A* v 201 n A4 1987 p 267-277.

**078867 BOLTED FLANGED JOINT LEAKAGE ANALYSIS WITH NON-LINEAR GASKET BEHAVIOR.** A model for the bolted flanged joint was developed; one which allows the evaluation of the gasket and bolt load by analyzing the equilibrium configuration. The sealing capability of the joint is checked when the load-leakage gasket correlation is known. A three-dimensional graphic analysis is discussed. An approximate formula is introduced to ascertain the flange ring rotation. Sample problems with non-linear gasket behavior are considered. (Author abstract) 4 refs.

**078868 EFFECT ON CONTACT HEAT TRANSFER ON THERMALLY STRESSED STATE OF THE FLANGED JOINTS OF A POWER PLANT PIPELINE VALVE.** An analysis of experimental and theoretical data has led to the conclusion that the most thermally stressed element in the design of a pipeline valve is the flanged joint. In a valve, three types of joint between the body and the cover are used: with integral (rigid) flanges, with detached (couple) flanges, and a combination of the first two, in which the bottom flange is an integral one and the top is a detached one. As an example, for designs of a wedge disc-type gate valve and of a control valve, the authors investigated the thermal state of the flanges of the two most widely used types in pipeline valves, i.e. with integral and detached flanges. 5 Refs.

## Friction

**078869 CONTACT PROBLEMS OF NIPPLE JOINTS.** In the presence of unidirectional couplings, when the region of contact and separation is unknown in advance, contact problems can be solved numerically using mathematical programming methods. The solution reduces to a system of inequalities in which various iterative algorithms are used to find contact zones and various expedients speed convergence of the iterations. In this paper the authors examine application of a trial method to solution of axisymmetric contact problems in the design of pipeline nipple joints. The computing scheme is constructed on the assumption that the union nut and nipple are absolutely rigid. The compliances of these elements of the joint are insignificant compared to those of the pipe and packing element, which are thin-walled. (Edited author abstract) 13 refs.

Rubin, A.M. *Sov Mach Sci* n 3 1987 p 98-101.

## Monitoring

**078870 ULTRASONIC MONITORING OF WELDED ANGLE-BUTT AND TEE JOINTS IN HIGH-ALLOY STEELS.** The feasibility of ultrasonic monitoring (USM) to evaluate the quality of angle-butt and tee joints in high-alloy steels is considered. Instructions have been developed for ultrasonic monitoring of welded angle-butt joints in chromium-nickel steels of the austenitic class. Experience with its use has indicated positive results in detecting defects of the crack and cold-spot type. For broader use of these instructions, however, it was necessary to investigate the effect of the structure and phase composition of the metal in the angle-butt joints on its acoustic characteristics, and to define the ultrasonic-monitoring regime more precisely as applies to welded joints in chemical apparatus. To confirm the effectiveness of ultrasonic monitoring of the quality of the welded angle-butt joints, the seams were radiographed

additionally by the method of gamma-radiography to expose most critical cold-spot-type defects in the root and along the edge of the seam, as well as cracks; this is confirmed by the results of a comparison made between the three methods of monitoring. Fine pores and individual slag inclusions cannot be detected with the same reliability. 5 refs.

## Testing See Also OFFSHORE STRUCTURES—Fatigue.

**078875 INVESTIGATION OF THE STRENGTH AND ENDURANCE OF WELDED T-JOINTS.** The authors have examined the results of theoretical and experimental investigations of the stress-strain state and carrying capacity of equal conduit T-joints of three different types made from steel and aluminum alloys during static and low-cycle stress due to internal pressure. The theoretical investigation was carried out using the finite element method which is applicable to the linear theory of thin elastic shells. As can be seen from the results obtained shifting in the weld joint changes the stress distribution along the coupling line. The experiments show that for T-joints tested at  $\sigma_n = 0.4-0.7\sigma_{1.0}$  the maximum value of  $e_{90}$  is observed in the section where  $\phi = 90^\circ$  and was 10-25%. On the basis of this investigation we propose a method for evaluating T-joints made of steel 12Kh18N10T. 7 refs.

## Aging

**078876 EFFECTS OF AGING ON POLYETHYLENE GAS PIPE.** The authors describe tests for the Gas Research Institute to determine the extent and effects of aging on buried plastic pipe. The results show that polyethylene pipe which has been in natural gas distribution service for as much as 20 years is not showing any evidence of physical or chemical aging. Compressed ring ESCR results appear unchanged over this time and residual stresses in pipe wall appear to be the same in aged pipe as in new pipe. Some pipe samples were found where a thin layer of the inner surface of the pipe has been oxidized, but this is not due to aging in the service environment since these samples were never used in a gas distribution system. However, hydrostatic pressure testing of these pipes shows how the presence of an embrittled inner surface layer in a polyethylene (PE) pipe may lead to a reduced service life. 8 refs.

**078877 RESEARCHERS PLOT THE LONG LIFE OF PE PIPE.** Already, tests have been completed that can be used to study the effects age has on plastic pipe. Results of the program indicate that polyethylene pipe - which has been in distribution service for up to 20 years - is not showing any evidence of physical or chemical aging. The Environmental Crack Resistance method was one test used. The effect of residual stresses on plastic gas pipe was also studied. The ring slitting technique was used to determine whether or not a decrease in residual stresses occurs in a service environment.

## Corrosion

**078879 CARBON DIOXIDE RESISTANCE OF AROMATIC AMINE CURED EPOXY FIBERGLASS OIL FIELD PIPE.** Aromatic amine cured epoxy fiberglass piping systems have been used successfully to handle oil field services requiring resistance to carbon dioxide. Laboratory and field test data verify the suitability of this type of pipe for these services. The laboratory study covers the effects of wet and dry carbon dioxide on aromatic amine cured epoxy fiberglass pipe under pressures from 300 to 850 psig (2.07 to 5.86 MPa). The oil field test data show the effects of 10 years of flowline service handling produced water saturated with gases containing carbon dioxide and hydrogen sulfide. (Author abstract) 12 refs.

## Cracking

**078880 INITIATION OF FRACTURES IN RIGID PVC PIPES BY SOFT PARTICLES.** Rigid PVC pipes prepared from a particle-free, tin-stabilized formulation were subjected to constant internal pressure tests (16 MPa, 60°C), originally in order to study the scattering in time-to-failure of pipes free from crack-initiating particles. Although many efforts were made to produce pipes free from all possible foreign particles, most failures were initiated by particles. The particles in this case were soft and rubbery. Particles of this kind have previously never been found in any of the several hundred fracture surfaces in lead-stabilized PVC pipes containing calcium carbonate studied in this laboratory. The possible origin of the soft particles is discussed. The results suggest that soft particles represent serious flaws. Besides a full-grown (penetrating) crack, some of the pipes also contained growing, particle-induced cracks. (Edited author abstract) 16 refs.

## Degradation

**078881 DEGRADATION AND STABILISATION OF BLUE WATER PIPE.** Degradation caused by natural and artificial exposure of blue polyethylene water pipe compounds has been studied using thermal, spectroscopic and mechanical testing techniques. The results indicate that whilst thermal properties can be used as an effective quality control tool, deterioration of mechanical properties corresponds rather more with carbonyl index measurements. Samples in thin and thick sections have been studied and differences in behaviour are noted, with thick section samples retaining mechanical (impact) properties even after substantial degradation has occurred. Limitations in the use of artificial exposure to monitor changes that occur during natural weathering are discussed. It is concluded that, in thick section, the surface nature of ultraviolet degradation in the extreme conditions of artificial exposure effects mechanical properties in a different manner than longer-term periods of natural exposure. (Author abstract) 3 refs.

**078889 SPECIAL HELICALLY WOUND PIPES FOR CAIRO WASTEWATER SCHEME.** Phase 1 of the Greater Cairo Wastewater Scheme has been instrumental in bringing forward many innovative ideas. Among them has been the use of the Helix process for the production of special pipe sections of up to six feet diameter for the discharge openings into the main sewer. The Helix process involves the extrusion of material at a melt temperature of 220°C and winding it with an overlap onto a preheated revolving and traversing mandrel. Complete fusion of the windings is achieved by a combination of infra-red preheat and the material's inherent self-welding properties. The result is a homogeneous mass with a weld-free smooth interior finish.

**078890 COEXTRUSION PROCESS FOR THE MANUFACTURE OF SHORT-FIBER-REINFORCED THERMOPLASTIC PIPE.** The advantageous use of short-fiber-reinforced thermoplastic (SFRTP) resins in the manufacture of pipe requires that the fiber orientation be controlled and that the surface finish not be adversely affected by the presence of the fibers. It is proposed here that a coextrusion process be combined with the use of a specially designed, expanding channel die to achieve these objectives. The use of a three-layer, coextrusion process in which unreinforced resin is used for both the inner and outer layers makes it possible to minimize the shear effects on the fiber orientation in the middle SFRTP layer. At the same time, it provides a smooth, fiber-free pipe surface. A theoretical analysis of this process is presented. The analysis shows that the presence of unreinforced surface layers increases the level and uniformity of fiber orientation. The results of an experimental study of fiber orientation in the middle SFRTP layer are found to be in qualitative agreement with the predictions of the theory. (Edited author abstract). 24 Refs.

**078891 TENSILE AND PRESSURE YIELD BEHAVIOR OF FLOWFORMED POLYPROPYLENE PIPE.** Flowforming is a cold-forming, rotary point

extrusion process. Polypropylene pipes were flowformed using a single roller on a conventional lathe machine to various degrees of percentage radial reduction ranging from 17 percent to 78 percent. In order to study the forces involved in the reduction process, radial, axial and tangential forces were measured. The flowformed pipes were tested under uniaxial tension and uniaxial pressure burst tests. Both the tensile strength and maximum hoop stresses of the pipes increased with percentage radial reduction. At high percentage radial reduction, the tensile strength increases more than 4-fold over the original tensile strength value. The extension at yield increases to a maximum at about 60 percent radial reduction after which the extension at yield decreases. Results from the pressure tests show that flowforming increases the ductility of the pipes. At large percentage reductions the pipes yield in a balloon-like manner. Various fracture phenomena are also presented. (Author abstract). 7 Refs.

**078892 EFFECT OF SHEAR ON FUSION AND MECHANICAL PROPERTIES OF RIGID PVC PIPES.** The shear level was increased during twin screw extrusion of PVC at different melt temperatures by inserting a hole plate in front of the screw tips. The variation of shear level did not significantly affect the capillary pressure in capillary viscometry at 135°C. However, the falling weight impact strength was markedly influenced. In internal water pressure tests at 60°C premature failure was obtained for pipes extruded at 198°C at the highest shear level. (Author abstract). 10 Refs.

## Performance

**078893 PERFORMANCE OF BURIED SMALL PIPES.** An analytical and experimental program was conducted to study the deflection and load-carrying capacity of small-diameter corrugated plastic drain pipes. The pipe samples were buried in different soils with various compaction conditions around the pipe. Measurements were taken of the vertical deflection and the pressure around the pipe under a wide range of surface loads. The most important parameters governing the pipe deformation are the pipe stiffness and the type and degree of compaction of the soil around the pipe. The variation of the modulus of elasticity of the pipe with deformation should be taken into account in pipe deflection prediction. The pipe stiffness was found to deteriorate under cyclic loading and unloading. (Edited author abstract). 11 Refs.

## Permeability, Mechanical

**078894 EVALUATION OF PERMEATION OF ORGANIC SOLVENTS THROUGH PVC, ASBESTOS/CEMENT, AND DUCTILE IRON PIPES.** Buried potable waterpipes are susceptible to permeation by organic solvents. In studying piping made of PVC, asbestos/cement, and ductile iron, full-pipe assemblies and laboratory bench techniques were employed. Elastomeric gaskets for all three systems become permeated, at least under exaggerated conditions. Results show that thermodynamic activity, as opposed to concentration, is the driving force. At solvent activities well above those encountered in typical soil, PVC is seen to be an effective barrier against permeation. (Author abstract) 14 refs.

## Stresses

**078895 STRAIN GAGE ANALYSIS OF RESIDUAL STRESS IN PLASTIC PIPES.** Residual stress distribution in medium density polyethylene (MDPE) 102 mm (4 in.) pipe with 11.1 mm wall thickness is evaluated using three different procedures. A modified layer removal procedure is employed to evaluate the residual stress component in the longitudinal direction as a function of the pipe wall thickness. On the other hand, the residual stress distribution in the circumferential direction is estimated using the conventional ring slitting method. A strain gage technique for direct residual strain measurements is described. The results obtained from the three procedures in a given direction are in qualitative agreements. A tensile residual stress dominates about 24% of the inner section of the pipe wall. The residual stress then becomes compressive reaching its maximum value at the outermost layer. (Edited author abstract) 18 refs.

**078896 INFLUENCE OF SURROUNDING SOIL ON FLEXIBLE PIPE PERFORMANCE.** The type of soil used to surround the pipes was found to have a considerable influence on pipe behavior. Various uncompacted granular materials provided good support, whereas uncompacted silty clay and silty sand did not. Compaction of the surrounding soil had a variable influence wholly dependent on soil type. Silty clay performed well only when thoroughly compacted in thin layers. Light compaction of a broadly graded granular soil improved performance slightly, whereas uniform gravel is generally considered to be unresponsive to compaction. The use of a thin bedding layer was shown to be beneficial in reducing pipe deformation, whereas a thicker bedding layer was shown to be less beneficial. The problems of measuring pertinent soil properties on site for fill selection are discussed and assessment of two empirical methods is made. (Edited author abstract). 10 Refs.

## Structural Design

**078897 STRUCTURAL DESIGN OF BURIED CORRUGATED POLYETHYLENE PIPES.** Minimum soil cover was investigated under multiple passes of live loads. Conditions for structural stability of the pipe were identified. An analytical procedure was developed for predicting the minimum height of soil cover to assure ring stability under multiple passes of live loads. Maximum soil cover tests confirmed the ring compression analysis as the primary basis for design but also revealed a need to include the effects of ring deflection. An observable performance limit was identified, and a method of design was developed that combined the effect of ring deflection and ring compression on the performance limits of CPEP buried under maximum height of soil cover. (Edited author abstract).

**078898 FRP PIPING DESIGN WITH THE AID OF THE SIMILARITY LAW.** By using this method, the strength of FRP pipes of the same laminate materials and laminate structure with different diameters can be predicted by a less experiment. In addition, the strength of the three-point bending, internal pressing and compressing destruction were calculated by the experiment, and these results were examined. Further, the designing method of FRP piping with the help of the similarity law is described after briefly reviewing the conventional method of the

strength analysis of fiber reinforced plastic (FRP) piping. (Edited author abstract) 4 refs.

**078899 FIELD PERFORMANCE OF CORRUGATED POLYETHYLENE PIPE.** Several Ohio Department of Transportation (ODOT) districts and Ohio county engineers have been using corrugated polyethylene pipe for small culvert replacements on a provisional basis since 1981. Use of this material by ODOT and the county engineers contacted has been limited to 12- through 24-in. sizes. Most culvert installations have been on secondary highways with no more than 6 ft of shallow cover. The structural and durability performance of all existing known corrugated polyethylene pipe culverts installed in Ohio was evaluated. This study was undertaken in February 1985 and completed in August 1985. A total of 172 culverts were inspected in 21 counties in Ohio. This article presents information pertinent to the structural performance and durability of corrugated polyethylene pipe culverts, which was obtained during the field data collection phase.

**078901 NOVEL TECHNIQUE TO INDUCE RAPID CRACK PROPAGATION IN TOUGH POLYMERS.** Pressurized plastic pipes, such as PE used for gas distribution, can be prone to catastrophic failure due to Rapid Crack Propagation (RCP). Once initiated, a brittle crack may propagate rapidly along the pressurized pipe for a considerable distance. Since initiation of cracks cannot be eliminated, PE pipes should be designed to ensure crack arrest as close as possible to the initiation site. In order to apply fracture mechanics concepts to this problem, the dynamic crack resistance of the material should be characterized. A new method for conducting reproducible and meaningful RCP experiments in simple, small-scale samples of tough PE grades was developed. The sample consists of a SEN plate of the tough polymer, with a glass slide adhered to the crack mouth. As the sample is being quasistatically loaded in tension, the glass stops the crack mouth from opening, carrying most of the load applied on the crack. Thus, it prevents the crack tip from blunting while the sample accumulates a sufficient amount of elastic strain energy. This note describes the novel method of propagating crack measurement. 5 Refs.

**078902 ELECTROFUSION JOINTING - THEORY AND PRACTICE.** Since 1969, when the British gas industry first introduced polyethylene (PE) systems for the distribution of gas, the vast majority of joints have been constructed using heated tool fusion techniques. The jointing processes (socket, saddle and butt fusion) employed have necessitated a high level of operator involvement in a difficult working environment and the continued availability on site of tools and equipment in good operating condition. Electrofusion fittings have good

potential for the simplification of socket and saddle fusion techniques using the minimum of equipment. British Gas have adopted the method for both new construction and repair operations.

**078904 DEVELOPMENT OF SEMI-AUTOMATIC FUSION EQUIPMENT AND A STUDY OF FUSION PARAMETERS.** Simplified semi-automatic equipment has been developed to carry out heated tool welding of MDPE tubes. In liaison with this automation, an investigation was carried out to quantify the heating time as well as the applied force. In addition, a study was made of the fusion parameters of PE pipe systems of 100 mm in diameter as well as of the temperature distribution in the axial direction, the shortening of the fusion zone due to pressure and the relationship between the strength of the fusion joint and the mean flow velocity of the fusion zone. **078906 ROHRE AUS NICHTROSTENDEM STAHL.** [Stainless Steel Pipe]. Welded pipes of stainless steels for the chemical industry were produced shortly after the invention of these materials, and were followed in the 20's also by seamless pipes. Today they are used also in other engineering fields, e.g., in the production of oil and gas, in pollution control, in power station construction and in automobile manufacture. The new technologies not only call for special material properties but also influence the manufacturing methods for producing stainless steel pipes. Thus, for example, pipes with reduced residual stresses and pipes with high degree of purity of their inner surfaces are currently produced. (Author abstract) In German.

## Bends

**078909 INVESTIGATIONS ON BENDING CONDITION FOR WELDED CARBON STEEL PIPE BY HIGH FREQUENCY INDUCTION HEATING.** The induction heating bent pipes of carbon steel welded pipes are used for the piping in nuclear power plants, in place of elbows. This application is useful to suppress the radiation exposure at in-service inspection. The quality of the bent pipes is controlled by the technical standards of welding for electrical equipment. However, the influence of the bending condition has not been yet sufficiently understood on the mechanical properties of the bent pipes. The purpose of this investigation is to establish the appropriate bending condition for the carbon steel weld pipe which corresponds to the carbon steel pipe STPT 42 in JIS G 3456, in relation to the transformation of the structures of the base metal and the weld metal during bending. (Edited author abstract) In Japanese. 3 refs.

**078913 CORROSION EXTERIOR DE TUBERIAS EN LA VIVIENDA: I PARTE. TUBERIAS DE ACERO.** [External Corrosion of Pipes in Housing - 1: Steel Pipes]. External corrosion of steel pipes in contact with Portland cement mortars and plaster is studied. Only low cement/sand ratios are considered. Specimens were tested in conditions of partial immersion in distillate water and also in environments with 50 and 100% of relative humidity. The effects due to the carbonation process as well as those due to the  $CaCl_2$  additions to the mortar were also determined. The corrosion monitoring was carried out by means of electrochemical techniques of measurement of instantaneous corrosion rate. Results clearly show the harmful influence of chloride additions. Plaster shows a harmful influence, except in very low humidity conditions. (Edited author abstract) In Spanish. 16 refs.

Huete, F.A. (Cent Natl de Investigaciones Metalurgicas, Madrid, Spain); Royuela, J.J. *Rev Metal (Madrid)* v 23 n 6 Nov-Dec 1987 p 402-412.

**078914 CORROSION EXTERIOR DE TUBERIAS EN LA VIVIENDA. II PARTE. TUBERIAS DE ACERO GALVANIZADO.** [Outside Corrosion of Pipes in Housing. Part 2. Galvanized Steel Pipes]. An attempt was made to follow during one year the corrosion process of galvanized steel pipes in contact with Portland cement mortars and with plaster, both in conditions of partial immersion in distillate water and also in environments with 50 and 100% of relative humidity. Results obtained showed an acceptable concordance between corrosion evaluations carried out by means of electrochemical methods and gravimetric determinations. Calcium chloride addition to the mortar signifies an increase of corrosion in one order of magnitude except in partial immersion conditions, in which a case no differences are observed. Plaster gives place to an intense attack, except when very low environmental humidity is maintained. (Edited author abstract) 10 refs. In Spanish.

## Crack Propagation

**078916 EFFECT OF PIPE BENDS ON THE STABILITY OF A CIRCUMFERENTIAL THROUGH-WALL CRACK IN A TYPE 304 STAINLESS STEEL PIPING SYSTEM.** The paper analyses simple models that simulate the effect of pipe bends on the stability of a circumferential through-wall crack in a Type 304 stainless steel piping system that is subject to fixed displacement loadings, which are appropriate for an accident condition. The instability criterion is expressed in terms of the applied and material tearing moduli, i.e.  $T_{APP}$  and  $T_{MAT}$ , or equivalently in terms of an effective pipe length  $L_{EFF}$ . By expressing  $T_{APP}$  (or  $L_{EFF}$ ) as a function of the position of the cracked section in the piping system, it is possible to specify the positions where  $T_{APP}$  is a maximum, and identify them in relation to the pipe bends. (Author abstract) 7 refs.

## Cutting

**078917 OPTIMIEREN DER ARBEITSBEDINGUNGEN BEIM ABSTECHE VON PREZISIONS-STAHLOHREN.** [Optimization of the Working Conditions in Cutting of Precision Steel Pipes]. Cutting to length belongs to the most difficult metal cutting processes, with only limited prediction of the machining results. The cutting to length of pipes, in particular precision steel pipes where the wall thickness is sometimes very small, is especially difficult due to requirements imposed on dimensional and shape accuracy and a good surface finish. Special tools have been developed for this purpose. The criteria for the process are tool life, cutting speed, feed rate, burr formation, and surface quality, as well as exact positioning and a good chip flow. (Edited author abstract) In German.

## Elastoplasticity

**078918 TWO-PARAMETER APPROACH TO ELASTIC-PLASTIC FRACTURE AND FAILURE ASSESSMENT DIAGRAM (APPLICATION TO CARBON STEEL FOR PIPING).** In a previous study, the elastic-plastic fracture toughness,  $J_{IC}$ , and the elastic-plastic fracture resistance curve (J-R curve) were evaluated by using compact specimens for a carbon steel, STS 42, used for piping in nuclear reactors. Based on those results, the applicability of the two-parameter approach to carbon steel piping was examined in this study. The construction of the failure assessment diagram (FAD) was also attempted. The results obtained are summarized as follows; (1) In the application of the two-parameter approach, it is essential to adapt the J-integral as a fracture criterion accounting for the strain-hardening effect. (2) Based on the FAD constructed, it is shown that the whole fracture process, from the fracture initiation to the unstable fracture (or the plastic collapse) including the stable crack growth, is predicted precisely for various sizes of specimen. **078919 DEVELOPEMENT DE NOUVEAUX ACIERS A HAUTES CARACTERISTIQUES POUR TRANSPORT DE GAZ ET DE PETROLE ACIDES.** [Development of New High Strength Linepipe Steels for Sour Service]. The use of pipelines under a more stringent environment has led to a change in demand for steel with improved strength toughness, weldability and HIC resistance. The paper describes the effect of the most important metallurgical parameters influencing the resistance of steel to  $H_2S$ . The HIC resistance is mainly controlled by cleanliness, segregation and rolling conditions. These three parameters were studied using 8 different steels covering a wide range of chemical compositions. Controlled rolling performed in austenite plus ferrite for the improvement of strength is detrimental for HIC resistance. Segregation of Mn, C and P leads to the formation of hard structures (bainite/martensite) at mid-thickness of the plates. These hard bands are sensitive to hydrogen cracking and must be avoided. Strict control of cleanliness, a low sulphur content ( $S < 0.002$ ) and shape control of inclusion (Ca treatment are important in improving HIC behaviour. The carbon-manganese balance has to be kept below a critical level in order to reduce the content and avoid the formation of hard segregated zones. 13 Refs. In French.

**078920 CORROSION-RESISTANT LININGS: THE CASE FOR PLASTICS GROWS STRONGER.** Plastic-lined pipes and vessels have been used in the chemical processing and related industries for about 30 years. They combine the corrosion resistance properties of plastics, particularly fluoropolymers, with the strength of steel housings. Courtauld's Advanced Materials has used a high-performance thermoplastic elastomer sheet to line a mild steel storage vessel in what is believed to be the first application of its kind. Recently, a fabric-backed version of the company's high-density polyethylene sheet has been introduced to complement Celmar in areas where polypropylene is not normally recommended, such as hypochlorite storage. Electrostatic build-up can be avoided using a technique in which a semi-conductive inner layer of PTFE carries induced charges to earth - preventing pin-holing and arcing - by surface conduction to the fittings.

Anon. *Process Eng (London)* v 69 n 8 Aug 1988 p 37-38.

## Magnetic Properties

**078921 MAGNETIZATION CHANGES INDUCED BY STRESS UNDER CONSTANT APPLIED FIELD IN 2% Mn PIPELINE STEEL.** Reversible and irreversible magnetization components have been derived from cyclic stress applied to initial magnetization curves at different magnetization levels and for different stress cycle amplitudes. The irreversible and reversible magnetization components derived were found to vary symmetrically and antisymmetrically with the applied stress, respectively. The variation of the irreversible magnetization component with applied compressive and tensile stresses was found to be in qualitative agreement with the extended Brown's theory of L. Brugel and A. Rimet. 14 refs.

Atherton, David L. (Queen's Univ, Kingston, Ont, Can); Rao, T. Sudersena; Schobachler, Markus. *IEEE Trans Magn* v 24 n 3 May 1988 p 2029-2032.

**078922 EFFECT OF APPLIED STRESS ON THE REVERSIBLE AND IRREVERSIBLE DIFFERENTIAL PERMEABILITIES IN 2% Mn PIPELINE STEEL.** The contributions of reversible differential permeability (RDP) and irreversible differential permeability

(IDP) to the total measured permeability have been derived from initial magnetization curves for a 2% Mn pipeline steel. In general, the effects of uniaxial stress on the IDP were significantly greater than on the RDP, and all the observed changes tended to be smaller at high magnetizations. At lower magnetization RDP tended to increase initially with tensile stress, while IDP was almost unaffected. On the other hand, compressive stress gave generally larger decreases both in RDP and IDP. The observed variations of RDP and IDP were, however, found to be complex functions of the magnetization. 16 refs.

## Manufacture See Also CARBON STEEL—Fracture; POWDER METALLURGY—Stainless Steel; ROLLING MILL PRACTICE—Pipe.

**078923 [NEUENTWICKLUNGEN IN DER TECHNOLOGIE UND BEI ANLAGEN FÜR DIE HERSTELLUNG KALTGEWALZTER STAHLROHRE IN DER UDSSR].** [New Developments in the Technology and Facilities for the Manufacture of Cold-Rolled Steel Pipe in the USSR]. The developments in the cold rolling technology in pipe manufacture proceeded in the USSR in recent years in two directions, namely, improvement of the existing rolling mills, as well as development of new high-performance semi-continuous ones. Further developments were towards the rise of the output of thin-walled pipes with both small diameters and higher precision and surface finish on ChPTV 15-30 type rolling mills combining the advantages of roll forming and grooved rolling as well as the use of flying mandrels during cold rolling. In cold drawing multiple mandrel drawing has been widely used. The use of special mandrels with flexible ends provides a stable mandrel position in the deformation zone and its easy removal after finishing the drawing operation. In linear drawing semi-continuous, three-strand draw-benches are employed. The use of specially designed die plates for drawing in plasto-hydrodynamic conditions results in a rise of productivity by 30% without the need for an essential equipment reconstruction. (Edited author abstract) In German. 9 refs.

**078924 THICKNESS VARIATION OF HOT ROLLED SKELP FOR PRODUCTION OF ELECTRICALLY WELDED PIPES.** The thickness variation of pilot plant batches of hot rolled skelp for electrically welded pipes was investigated to establish the possibility of reducing metal consumption. Investigations were carried out with the use of an X-ray thickness gage whose transducer was moved back and forth across skelp travelling at speeds of 0.8-1.0m s<sup>-1</sup>. Thickness was recorded by a recording potentiometer. Similar investigations were made of the thickness variation of hot rolled coil steel, but in this case with the thickness gage transducer in a stationary position at entry into the forming mill. Results enabled the optimum thickness of skelp to be established for the production of water and gas linepipe. (Author abstract) 2 refs.

**078928 COLD DRAWN ERW PIPES WITH SUPERIOR FORMABILITY.** Cold drawn ERW pipes sometimes show the difficulty in formability during cold working, expanding, and swaging because of the difference in recrystallization behaviors between the welded zone and base metal in cold drawing. In this report, recrystallization behavior was on the results, a uniform recrystallized microstructure is established by post heat treatment of the welded zone or control of the chemical composition and rolling conditions in manufacturing of hot-rolled coils. Cold drawn ERW pipes with superior formability are thus produced. (Edited author abstract) 2 refs.

**078929 MANUFACTURE AND PROPERTIES OF 9 CR STEEL LARGE DIAMETER PIPE.** 9 Cr ferritic steels have been studied as an alternative material for high-pressure parts in fossil-fuel fired power plants. These parts include main steam pipe and header applications, for which 2.25 Cr-1 Mo steel is currently being used. The increased chromium content of 9 Cr steels produces higher oxidation resistance than 2.25 Cr-1 Mo steel, and the elevated temperature strengths of these steels are also high. Furthermore, these steels, compared with austenitic stainless steels, provide advantages in terms of cost reduction and reduction of the thermal stresses generated during field operation. This work confirmed that 9 Cr steels are applicable to large diameter heavy walled pipe. Effective procedures for manufacturing this pipe have also been established. (Edited author abstract). 19 Refs. In Japanese.

#### Nondestructive Examination

**078932 ELECTROMAGNETIC FLAW DETECTOR EDI-03 FOR CHECKING WATER-AND GAS-LINE PIPE IN THE HOT STATE.** One of the ways of improving the reliability of pipes is providing for their nondestructive inspection for flaws early in the production process. This makes it possible to correct the defects in time and avoid rejection of the product. As regards the production of pipes for water and gas lines by furnace welding, providing such inspection has been hindered by the high process temperatures of the pipes (up to  $1200^\circ\text{C}$  on the delivery side of the forming-welding mill). To solve this problem, the Scientific-Research Institute of Electronic Flaw Detection and the Chelyabinsk Pipe Plant collaborated to develop an electromagnetic flaw detector to check pipes with an outside diameter of 80-90 mm and temperatures up to  $1300^\circ\text{C}$  moving at speeds up to 5 m/sec. The sensitive elements of the eddy current transducer of the detector are protected from overheating by a water cooling system.

**078933 DEVELOPMENTS IN THE DUAL-PROBE TECHNIQUE FOR IMMERSION ANGLE-BEAM ULTRASONIC TESTING OF STEEL TUBE AND PIPE.** Use of the dual-probe technique is proposed for immersion angle-beam ultrasonic pipe testing. This technique can give a steadier and more stable surface echo than the one obtained by the conventional single-probe technique. The acoustic coupling can be monitored and the start point of the gate and distance-amplitude correction can be controlled. The validity and usefulness of this proposal has been proven by both analytical calculation and experimental data. The development of a model of the proposed probe is described. The developed probe has contributed significantly to updating of rotating-probe ultrasonic testing equipment for steel tube and pipe. (Author abstract) 2 refs.

#### Protective Coatings

**078936 CHARACTERISTICS OF NEWLY DEVELOPED POLYPROPYLENE COATED STEEL PIPE FOR HIGH TEMPERATURE SERVICE.** Polypropylene extrusion coating has been developed for external corrosion protection of steel pipes for high temperature service. The coating can be used for corrosion protection between  $-30^\circ\text{C}$  and  $120^\circ\text{C}$ . Main disadvantages are brittleness at low temperature and long term durability at high temperature. The former has been solved by block copolymerization with ethylene and the latter has been solved by the addition of specific antioxidants. The estimation technique called oven aging method is more accurate than the measurement of oxidative induction time. (Edited author abstract) In Japanese. 6 refs.

#### Spectroscopic Analysis

**078939 SURFACE AND THERMAL DESORPTION INVESTIGATIONS OF CHEMICALLY CLEANED 316-L STAINLESS STEEL TUBINGS.** When dealing with high purity gas handling, the nature of metallic surfaces in contact with the gas is a major concern because these surfaces are a possible source of gaseous pollution. Several surface treatments may be applied to

stainless steel tubes used in gas handling systems, and these lead to different desorption properties. A comparison of the topographical effects accomplished by roughness and SEM measurements, and chemical effects by XPS determinations was made. Results were correlated to the outgassing behaviour of 316-L SS surfaces, as determined by thermal desorption mass spectroscopy. It appears that similar treatments of 316-L SS may not result in similar outgassing properties. Electropolished surfaces are smoother and present the least outgassing, although carefully cold drawn and chempolished stainless steel surfaces also show a comparable outgassing behaviour. (Author abstract) 5 refs.

## Testing

**078940 MULTI-STEP APPROACH FOR EVALUATION OF PIPE IMPACT EFFECTS.** A methodology has been developed and applied to the requalification of the high-energy piping at the Santa Maria de Garona Nuclear Power Plant in Spain. It provides techniques for evaluation of pipe-whip and jet effects. The methodology developed breaks down the evaluation effort into various levels of decreasing conservatism and increasing complexity and cost. Higher evaluation levels are applied only to interactions where lower levels fail and where there is a reasonable expectation that more realistic analysis might demonstrate acceptability. The lower levels of evaluation are described in this paper for the pipe-on-pipe impact interactions, targets other than pipes are relatively straightforward. (Edited author abstract) 6 refs.

## Wear

**078941 BREAKTHROUGH IN ABRASION RESISTANT PIPING.** NASPipe, the abrasion-resistant carbon steel pipe from Canada, is unlike many of the conventional abrasion-resistant products presently in use in that it is not cast and it does not rely on synthetic or ceramic liners. In the manufacturing process, the pipe chemistry is changed, resulting in a pipe with an internal bore of at least 600 Brinell hardness, but with physical toughness and ductility similar to normal steel. Hardening is achieved by induction heating and quenching and it is during this phase that the pipe can be bent to almost any centerline radius or bend angle required.

**078945 STUDY ON INTEGRITY IMPROVEMENT OF STAINLESS STEEL PIPE WELDS IN NUCLEAR POWER PLANT BY LOCAL INDUCTION HEATING METHOD.** In order to eliminate tensile residual stresses near the weld heat affected zone on the inner surface of Type 304 stainless steel pipe welds in nuclear plants, the induction heating stress improvement (IHSI) method, in which the outside wall of a pipe is heated by an induction current while the inside surface of the pipe is cooled with water, has been investigated analytically and experimentally. This method has been found to be effective in reducing the fatigue crack propagation rate of cracks in pipes under the repeated loading associated with plant operation and in preventing the intergranular stress corrosion cracking. Test results showed that compressive residual stresses relax under certain circumstances, but that the compressive residual stresses on the inner surface of a pipe do not relax during operation enough to cause them to change into tensile stresses large enough to cause intergranular stress corrosion cracking. (Edited author abstract) In Japanese. 10 refs.

**078952 ON THE GENERATION OF ACOUSTIC RESONANCE IN PIPELINES - PART 1.** An experimental and theoretical study has been conducted to investigate acoustic resonance in a pipeline caused by a pipeline singularity. A pure tone noise source in the form of a double orifice was used and the nature of the fluid excitation mechanism was studied using flow visualization. It was found that free shear layer oscillations across the cavity formed by the double orifice excite those pipeline plane-wave modes which have an acoustic velocity antinode at or near the cavity. Experimental results are presented for resonant frequencies as a function of flow velocity, and Strouhal number as a function of the cavity dimensions. The theoretical predictions for acoustic resonant frequencies are compared with the experimental data. This paper described the experimental facility for the research. (Edited author abstract)

Harris, R.E. (McMaster Univ, Hamilton, Ont, Can); Weaver, D.S.; Dokainish, M.A. *Pipes Pipelines Int* v 33 n 1 Jan-Feb 1988 p 30-32.

**078953 ON THE GENERATION OF ACOUSTIC RESONANCE IN PIPELINES - PART 2.** The first part of this paper, published in our January-February issue, considered the experimental facilities used in the authors' research. Part 2 goes on to describe the experimental techniques employed, and provides a discussion of the authors' results and conclusions. The main characteristics of a resonator exciting the plane-wave modes of a pipeline have been illustrated. The acoustic source has been shown to exhibit the main features of local cavity oscillators. The results of the flow visualization study indicate the presence of a rolled-up shear layer, and not the convection of separated vortices. 21 refs.

## Automatic Testing

**078955 METHOD OF PIPELINE DIAGNOSIS BY A MOBILE ROBOT.** A newly designed articulated mobile robot of variable-attitude type, the Mark II, which consists of three modules with a joint between modules, has the capabilities of straight and spiral movement along the outside of pipelines, and of free passage of obstacles, such as flanges, T-joints and other plant equipment. The robot uses its front-installed infrared proximity sensors to sense and recognize T-joints. A method of controlling maneuverability in the passage of T-joints is achieved by calculating the positions and attitudes of each module of the robot. To inspect any arbitrary position in a pipeline, a method of compensating independently for the torque generated by gravitational forces for each module is proposed. Based on the inspection results of a modeled pipeline having a T-joint and flange, it has been clarified that the Mark II installed with non-contact gap sensors as diagnostic sensors can detect not only the position of

flaws, but also their depth. 6 refs.

**Bends** See Also FLOW OF FLUIDS—Laminar; FLOW OF FLUIDS—Two Phase; STRESSES—Analysis.

**078956 ANALYSIS OF PIPE BENDS WITH SYMMETRICAL NONCIRCULAR CROSS SECTIONS.** A thin shell analysis is presented for pipe bends with symmetric noncircular cross sections under in-plane bending or internal pressure, using the static-geometric analogy and neglecting end effects. Any symmetric shape is possible but the analysis mainly concerns cross sections with double symmetry; an investigation of the two-lobe (oval) and four-lobe cross sections demonstrates that pipe bend flexibility is almost inversely proportional to flank radius if the pipe wall is thin. Pressurizing a pipe bend of oval cross section produces a similar hoop stress distribution to that of a bending moment straightening the pipe. (Author abstract) 6 refs.

Whatham, J.F. (Australian Atomic Energy Commission, Sutherland, Aust). *J Appl Mech Trans ASME* v 54 n 3 Sep 1987 p 604-610.

**078957 STIFFNESS OF A CURVED SECTION OF PIPE IN BENDING.** The problem of determination of the stiffness and state of stress of a curvilinear pipe section joined to straight pipe sections and subjected to the effect of bending and internal pressure is considered. Apart from the main state of stress, account is taken of the boundary effect state in accordance with the moment engineering theory of shells. The method developed for the determination of the stiffness in bending of curvilinear pipe sections may be recommended for use in calculating and designing piping systems. 5 refs.

**078958 CAST-STONE SECTORS FOR LINING BENDS IN PIPEWORK.** An effective method of prolonging the useful life of the process pipework between maintenance shutdowns is to protect it with cast-stone which has a high abrasive-resistance and is stable against chemical attack by acid media. Large-scale ring sectors of diameter 680 to 1165 mm were cast in a horizontal centrifugal machine. Before the melt is cast into the mold, steel ring partitions are mounted at a specified angle to the axis and these are secured by ring inserts made of reinforcing mesh. The end covers are closed and the substrate is rotated at 280-300 min<sup>-1</sup> and, by means of the spout, the silicate melt is cast at 1320-1360°C. The use of this method makes it possible to produce cast-stone sectors with a tongue-and-groove end which provides a dense and reliable protection for the butt seams when the lining is installed. To avoid crazing in the cast, it is necessary to ensure that the central rod is pliable after casting and this is done by forming a shell with a wall thickness of 8-10 mm.

**Cathodic Protection** See Also ANODES—Materials.

**078960 CATHODIC PROTECTION MONITORING ON BURIED PIPELINE SYSTEMS BY CLOSE INTERVAL POTENTIAL SURVEYS.** Continued development of site data collection equipment and the introduction of computer assisted data processing systems has allowed the cathodic protection engineer to obtain more comprehensive site measurements which can be used to improve the overall performance and effectiveness of the installed systems. A procedure which ideally lends itself to this technology for buried pipelines is a close interval pipe to soil potential survey. The success of this method for the determination of unpolarized coating fault and cathodic protection deficiencies has been effective to the point where dedicated systems for this work are readily available.

Anon. *Anti Corros Methods Mater* v 34 n 8 Aug 1987 p 17-18.

**078961 PROTECTION OF PIPELINES FROM CORROSION BY CATHODIC PROTECTION.** Pipelines are one of the most convenient means of transporting low-viscosity material, such as gases and liquids, from supplier to consumer. Buried pipelines can deliver the product over great distances with minimal, if any, inconvenience to the public. However, long, buried pipelines represent a high capital investment which must be protected if the pipeline is to operate cost-effectively with minimal maintenance over long periods. Public safety must also be considered, and pipelines must be free from the risk of degradation which could cause environmental hazards and a potential threat to life. They must be protected from corrosion. Soil stresses and damage during backfill can cause superficial damage which exposes the base metal, leaving it vulnerable to corrosion. The paper discusses the method of cathodic protection as a means to prevent corrosion damages on pipelines.

Shepherd, W. (Wilson Walton Int (UK) Ltd). *Pipes Pipelines Int* v 32 n 4 Jul-Aug 1987 p 18-21.

**078962 MONITORING PIPELINE CATHODIC PROTECTION.** Electrically speaking, a pipeline represents a complex conductor installed in a complex environment - the earth. To ensure adequate corrosion protection, every measure is taken in the design stage to minimize corrosion effects. The overall umbrella is provided by the cathodic protection system, which essentially stops corrosion from occurring at defects and anomalies in the pipeline coating system. As pipelines are put into service, various anomalies begin to show up and it is a rare circumstance when a pipeline is totally free of all defects.

Rog, Joseph W. (CORRPRO Co, Medina, OH, USA). *Pipeline Gas J* v 215 n 2 Feb 1988 p 14-17.

**078963 EVALUATING DESIGN AND COST OF PIPE LINE COATINGS - PART 1.** TransCanada PipeLines uses several methods to assess the performance of its coatings system on more than 10,000 km of large diameter gas lines. In this first installment, the author describes the correlation between field performance and laboratory testing of the various coatings. He also provides guidelines for selecting an effective repair or recoating system.

Banach, J.L. (TransCanada Pipelines, Toronto, Ont, Can). *Pipe Line Ind* v 68 n 3 Mar 1988 p 62-67.

**078964 PROBLEME DER IR-FREIEN POTENTIALMESSUNG IN GEGENWART VON AUSGLEICHSTROMEN.** [Problems Related to the Measurement of IR-Drop Free Potentials in the Presence of Compensating Currents]. For supervision of the cathodic protection of pipelines the potentials must be measured free from ohmic drops. In general, off-potentials are measured in this context. By this technique only the ohmic drops caused by the protection current can be eliminated, but not the ohmic drops caused by compensating or cell currents. With the help of simulated tests it can be shown

that it is possible to calculate true potentials using pipe-to-soil potentials and potential gradients at the soil surface for 'on' and 'off' conditions. Errors associated with reference electrodes have a strong influence on the calculated values. Practical examples show that completely unreasonable values can be obtained. Possibilities leading to errors of reference electrodes are discussed. Electrodes with KCl or  $N_4NO_3$  electrolytes are to be preferred. Further possibilities of errors related to soil parameters require additional detailed investigations. (Author abstract) 6 refs. In German.

## Cleaning

**078965 KINETICS OF PIPELINE CLEANING BY FOAMS.** The authors studied the factors influencing the efficiency of pipeline cleaning by foam. Experimental data show convincingly that 1% AS solutions used in the form of foams of 200-500 ratio are the most effective agents for removing gas condensate. The cleaning efficiency is improved by addition of HAA in amounts of 10% on the mass of surfactant. Foams based on SEO solutions (1% surfactant) do not differ significantly in efficiency from AS-based foams. Of the three types of surfactants studied the least effective is the nonionic Prevoell, since it has the lowest surface activity (this is the cause of the low foaming power of its solutions and poor stability of its foam in contact with the gas condensate). For effective cleaning the average foam velocity in the pipe must be at least 9-10 m/sec. The open cross section of the pipe must be completely filled with moving foam. 4 refs.

Tikhomirov, V.K.; Goncharov, V.N. *J Appl Chem USSR* v 60 n 1 pt 2 Jan 1987 p 197-200.

**078966 PIPELINE CLEANING SYSTEM FOR MECHANICAL DEPOSIT REMOVAL.** Pipelines in which deposits occur frequently must be cleaned in course of time to avoid loss of flow capacity. The Idromec system for mechanical deposit removal has proved itself to be particularly suitable. Main features are: effective cleaning of all viscous and hard deposits; restoring original flow capacity for pipes with diameter of 100mm to 200mm; cleaning speed 0.5m/s to 1.5m/s; no damage to inside walls or protective lining; no corrosion or abrasion cleaning vertically rising pipelines clearing elbows of 90° with radius  $\times$  1.5 pipe diameter. Generally, Idromec is applied in all those cases where pipeline cleaning is not possible by either chemical methods, high pressure water jets, motorised flexible rods or by using pigs. The cleaning is effected by a hydromechanical method, using specially designed tools. 4 refs.

Anon. *Eur Water Sewage* v 91 n 1097 Jul 1987 p 283-284.

**078967 INTERACTION OF A MOVING FOAM WITH GAS CONDENSATE IN PIPELINE CLEANING.** The purpose of this paper is to discuss a possible mechanism for foam interacting with contaminants during pipeline cleaning. The authors consider the flow of a foam as that of a single-phase system while the properties  $\rho$  and  $\nu$  of the foam are constant, as the measurements for different foams are averaged. It is found that the higher the foam speed in the cell (the less the diameter), the greater the drop in cleaning rate. At low foam speeds ( $d = 55$  mm), the rate of removal for a gas condensate is practically constant throughout, because the main part is played in the initial stage by the dynamic action of the foam on the layer of gas condensate at rest, which causes mechanical expulsion of some of the material from the cell. For cells of diameter 28 and 36 mm, this effect accounts for up to 50 or 25% of the material. 6 refs.

## Computer Aided Analysis

**078968 DISTRIBUTED PARAMETER IDENTIFICATION OF A PIPELINE USING A SENSITIVITY MODEL.** The purpose of identifying diameter and/or friction distribution of a pipeline is threefold: (1) to diagnose pipeline faults; (2) to calibrate a mathematical pipeline model and (3) to monitor the state of the pipeline during operation. In this paper, a technique is proposed to estimate an arbitrary diameter distribution  $D(x)$  of a pipeline. Output least-square criterion is used which results in a gradient-based estimation algorithm. The gradients are evaluated from a parameter-sensitivity model alongside of the real-time pipeline model. (Edited author abstract) 12 refs.

## Computer Aided Design

**078969 SEADRIFT CUTS DRAFTING TIME WITH DESKTOP COMPUTERS.** Seadrift's engineering department maintains more than 25,000 drawings of Seadrift's pipe line control systems, which include electrical, microwave, structural and telecommunications systems. Virtually all new drawings for the company, as well as existing drawings requiring major revisions, are created and stored on the desktop computers. Seadrift's three designers use AutoCAD software running on the MS-DOS operating system on the IBM computer. AutoCAD acts as an electronic drafting board and users input drawings, then move, copy, erase, rotate, stretch, trim or extend the drawings onscreen. Seadrift designers also employ a special software interface written for the AutoCAD system by personnel at the MicroAge Computer Store in San Antonio. The interface allows the designers to create and store symbols for electrical and control systems design.

**078971 NUMERICAL STUDY OF THE EFFECT OF SUPPLY AND DELIVERY PIPELINE RESISTANCE ON THE OPERATION OF A SAFETY VALVE.** The authors have developed a package of programs in PL/I language for the calculation of on steady-state processes taking place as a result of high pressure in a supply pipeline (tank) and of safety valve wear in a system consisting of a tank (or compressible fluids) supplying a pipeline, a safety valve (SV), and a delivery pipeline. The authors illustrate the use of this package by the example of a calculation of the wear process in a direct-action full-rise SV in a pneumatic system consisting of a tank and a supply pipeline. The program package can be used to study the effect of supply

and delivery pipeline parameters on the nature of the SV's operation; to develop engineering methods for the calculation of pipeline parameters other than a valve's slide vibrations (however, such calculation methods can apparently be developed only for concrete valves, since the stability of a valve's operation depends to a great extent on the shape of the force characteristics); and to model emergency situations that lead to abrasion of the SV. It can also be used to study the operation of any type of accessory, such as regulators, check valves, etc. 6 refs.

**078974 COMPUTERISED PIPELINE SYSTEM FOR OPERATIONAL SURVEY COLLATION AND ARCHIVE RETRIEVAL (OSCAR).** The rapid retrieval of paper documentation from the construction phases of a pipeline project presents a major task which becomes increasingly more difficult with time. The production of more paperwork from each inspection survey carried out means that archive management and storage requirements increase annually. Furthermore, experience from many projects has shown that important data is often lost or very difficult to find when needed quickly to support the decision-making process. OSCAR (Operational Survey Collation and Archive Retrieval) is designed to provide a low-cost computerised solution to data management for project and operations groups throughout the life of a pipeline.

Marshall, Greg (Marshall Marlow Associates). *Pipes Pipelines Int* v 32 n 6 Nov-Dec 1987 p 23-24.

**078975 TRENCHLESS REVOLUTION.** The principal technical advances in recent years for the construction of new underground services have been the trenchless methods: improvements in unsteerable percussive moles; the development of steerable small-bore models; the development of steerable auger-type microtunneling machines for installing pipes down to 250 mm diameter; the development of steerable bentonite slurry-type microtunneling machines for installing pipes down to 250 mm diameter. Over much the same period there have been equally striking advances in techniques for renovating and replacing (on-line) existing buried services, including: slip

lining; spray-on linings; rolldown; hose inversion; percussive on-line replacement; hydraulic on-line bursting and replacement. 5 refs.

**078976 PIPELINE PIGGING - AN INDUSTRY OVERVIEW.** Rapid technological change, combined with strong social and economic pressures, have resulted in a rate of change within the pipeline pigging industry which was unimaginable just a few years ago. This paper highlights many of these changes, covering both their causes and effects, and attempts to draw some conclusions as to what may lie ahead. Mention is made of subsea pigging systems, briefly commenting on the overall layouts, pig traps, signalers, etc., with mention of the companies currently involved. This is followed by a look at the situation with respect to intelligent and conventional pigs. The paper also considers the present trends in the exploration and production of hydrocarbons, particularly in deeper waters and marginal conditions, and attempts to predict how this is likely to affect development within the pipeline pigging industry in the foreseeable future. 2 Refs.

**Control** See Also GAS PIPELINES—Computer Applications; NATURAL GAS PIPELINES—Communication Systems.

**078977 ROBUST OBSERVER DESIGN FOR A FLUID PIPELINE.** Observer design for nonlinear systems is difficult, especially for systems of high order. We present a state-space representation of a fluid pipeline. Then we turn the nonlinear observer design task into optimization problems in order to bridge the gap between nonlinear observer theory and its applications. In applying this method to the discrete high-order model of a pipeline, analytic solutions can be obtained. A structural condition for observers to be robust to pipeline friction and diameter variation is proved through steady-state analysis. Simulation studies and experiments on a water pipeline show that: (a) the observers designed converge rapidly and reliably; (b) the computational expenditure is small in comparison with the Kalman filter; and (c) friction and diameter variations may have little influence on the estimation accuracy. **078978 EFFECT OF POWERLINE FAULTS ON PIPELINES IN A COMMON CORRIDOR.** The report summarizes the study of power line fault effects on pipelines in a common corridor. Phase 1 has concentrated on establishing a laboratory set-up that will permit the simulation of field conditions for pipeline damageability studies. A facility has been set up at Ontario Hydro Research that will permit the effect of varying fault conditions and pipeline parameters to be studied. Initial experiments have been performed primarily at 10 and 20 kA for 6 and 12 cycle durations. The damage on the pipeline has been quantified in terms of its fault condition, damage diameter and depth. The experimental results have been compared to actual field failures and other related research work. (Edited author abstract) 8 refs.

**078982 COMPARISON OF GERMAN TO MARSTON DESIGN METHODS.** In the United States and several other countries around the world, the Marston load theory is commonly used in computing the trench backfill loads on rigid pipes. Germany is using an alternative method developed by Abwassertechnischen Vereinigung e.V. (ATV) as the working design method for rigid and flexible pipe. This paper presents the German design method and a comparison of the two theories as they are applied to buried vitrified clay pipe design. The load ratio is defined as the ratio of the German load to Marston load. This ratio that the Marston theory is conservative for small pipes backfilled with well-compacted granular material because it neglects the load relieving effect of the side fill and underestimates the friction between backfill soil and trench walls. The effects of the trench geometry, soil characteristics, the pipe diameter, and the stiffness ratio of bedding and backfill soils on the trench loads are studied in detail for both German and Marston methods of design. (Edited author abstract) 9 refs.

**Earthquake Resistance**

**078983 DISTRIBUTION OF SEISMIC HAZARD AND RISK ANALYSIS OF BURIED PIPELINES IN TAIWAN.** Based on the seismicity and tectonics of Taiwan area, a set of potential earthquake sources is identified. Using available attenuation laws and fault-rupture model, the individual influences of potential sources are integrated into the probability distribution of maximum annual intensity and peak acceleration. The results are presented in the form of seismic risk maps for a 475-year return period. Based on the result of this study, it concludes that the seismic hazard potential for the central region is moderate, but it is high for east-coast region. This paper also presents a reliability analysis method for safety evaluation of buried pipelines in Taiwan region. The result of the reliability analysis of the buried pipelines subjected to earthquake ground accelerations are presented and a fragility result for peak ground acceleration (PGA) studies is also constructed. (Author abstract) 15 refs.

**078985 FEM STUDY OF GROUND STRAINS FROM STRONG MOTION ARRAY DATA FOR LIFELINE APPLICATION.** The seismic behavior of lifeline systems is predominately controlled by the ground displacement/strain characteristics. This study investigates the wave propagation effect. Ground displacements and ground strains from the latest strong-motion array data recorded at the Public Works Research Institute (PWRI) of Japan by using the finite element method. Usually, the movement of the buried pipeline is almost the same as that of the surrounding soil during seismic shaking. In this respect, the investigation of ground displacement characteristics can be used for further applications to the seismic design of buried pipelines. (Edited author abstract). 21 Refs.

Yeh, Yaw-Huei (Nat'l Taiwan Inst of Technology, Taipei, Taiwan); Wang, Leon Ru-Liang. *Chung kuo Kung Ch'eng Hsueh K'an* v 11 n 3 May 1988 p 207-218.

**078986 ANALYSIS OF CONTINUOUS BURIED PIPELINES FOR SEISMIC WAVE EFFECTS.** An analysis procedure for seismic wave propagation effects on straight continuous buried pipelines is proposed. It is shown that ground strain due to surface waves can be substantially larger than that due to body waves. An elastic model of a buried pipeline surrounded by equivalent soil springs indicates that frictional slip between the pipeline and the surrounding soil springs is likely for high ground strains. A method for estimating ground strain due to surface waves, based on data from the 1971 San Fernando earthquake, is reviewed. An analysis procedure, which utilizes frictional forces near the soil-pipeline interface, is proposed for surface wave effects on straight buried continuous pipelines. (Edited author abstract). 33 Refs.

**Fabrication**

**078990 PIPEWORK PREFABRICATION - THE ECONOMICS.** Prefabrication shops should not be limited to prefabrication of pipe for one contract at a time as, dependent on size of shop, two or three contracts could be taken 'in house' for other contractors. Therefore, in a very short space of time, one can see a return on capital invested, and within one or two years, a handsome profit on investment. Author details the main costs of on-site prefabrication in comparison to workshop prefabrication. Expenses for labour to get to site need to be paid, as well as weekly, or monthly costs of materials delivered to site. Production time is lost on site due to bad weather if prefabrication is not done in a covered area, as well as if accidents happen. The costs for a prefabrication shop would only be for materials, which could be bought in bulk thus saving on purchasing costs for each contract.

**078991 PLASTIC COLLAPSE ANALYSIS OF GIRTH WELD REPAIR GROOVES IN PIPE SUBJECTED TO OFFSHORE LAYING STRESSES.** The overload failure of pipes containing girth weld repair

grooves subjected to offshore laying stresses was investigated. Repair welding trials were conducted on full scale pipe sections, and tensile tests on weld metal and parent metal were performed at elevated temperatures in order to determine whether or not heat from the welding process would result in a loss of strength locally. A new plastic collapse solution for circumferentially notched pipes in bending was derived. This analysis can be used to predict failure in pipes containing part-wall or through-wall repair grooves at various circumferential positions. Four-point bend tests on small scale pipe sections were performed. (Edited author abstract) 7 refs.

**078992 ESTIMATION OF THE UNSTABLE FRACTURE OF PIPE WITH A CIRCUMFERENTIAL SURFACE CRACK.** Several criteria are proposed to predict the failure bending moment of a pipe which has a circumferential crack and is subjected to external bending moment in LWR (Light Water Reactor) pressure boundary piping. However, those criteria give an unconservative prediction when the pipe has a short and deep circumferential surface crack. This paper presents a half-empirical criterion on the basis of the test results. This criterion gives a conservative prediction by choosing the optimum parameter, even if the pipe has an arbitrary circumferential surface crack. This paper also presents a method to calculate a tearing modulus,  $T_{app}$ , of the pipe containing the circumferential surface crack just after the ligament failure. (Author abstract) 13 refs. **078994 EFFECT OF GAS EXPANSION ON SLUG LENGTH IN LONG PIPELINES.** One of the important parameters in slug flow is the length of the liquid slug. Slug length is important in determining the average pressure drop as well as fluctuations in the pressure. Moreover, knowledge of the length of the slugs leaving long pipelines is crucial for the design of slug catchers. For short pipelines, the slug length is determined by the entrance phenomenon and by the stability of the slugs. For long pipelines the situation is not entirely clear. Long slugs may be formed due to terrain slugging. In this work, it is shown that long slugs can also be formed due to the decrease in pressure in the downstream direction. (Author abstract) 17 refs.

**078997 FLUID MECHANICS OF CAPSULE PIPELINES (5TH REPORT, ANALYSIS OF THE CAPSULE VELOCITY, DRAG COEFFICIENT AND DESIGN OPTIMIZATION).** The most important problem in the study on a flow of capsule transport is to clarify the characteristics of pressure loss and capsule velocity in the turbulent flow regime. In this capsule pipelining series, the authors have mainly reported fundamental work on the pressure loss of cylindrical capsule flow. The present paper describes the theoretical prediction of capsule velocity and discusses the optimum situation of transport. The capsule velocity is determined after consideration of the agreement between the pressure loss formed by geometric capsule conditions and the pressure drop required to move capsules steadily. The predicted velocities are in good agreement with reliable experimental data. In this report through a numerical calculation simulating various capsule-flow conditions, the optimum velocities for minimizing power consumption and pressure loss, respectively, become evident. (Edited author abstract) 10 refs. In Japanese.

**078998 DYNAMICS OF THE FREEZING OVER OF UNDERGROUND PIPES.** Pipeline transport of water, aqueous solutions and suspensions under conditions of low ambient temperatures may be accompanied by their freezing. The formation of an ice layer on the inner pipe surface causes increased hydraulic resistance. In view of that the prediction of freezing over of pipes under extreme climatic and technological conditions has to be included in the pipeline project. This article suggests a method of calculating the unsteady process of freezing over of an underground pipe transporting a freezing liquid. 11 refs.

**078999 MOBIL'S PIPE FREEZE BREAKS NEW GROUND.** The authors report an interesting and complex pipefreezing operator carried out in 1986 at the base of the North Sea's Statfjord A platform, 150 m below sealevel. Using nitrogen liquid at  $-196^{\circ}\text{C}$ , MCL froze a succession of pipes in the base of the condeep structure to form plugs of sufficient strength to allow removal of

corroded pipe sections and their replacement. The work involved 16 separate freezes on pipes of 18in diameter at the base of the structure approximately 150m below water line and 175m below deck base level. The work was carried out from June to August last year, after extensive trials in 1984 and 1985 held in Norway and approved by all parties involved, including DNV.

**079000 OPERATION 'DEEP FREEZE'.** Corroded pipe sections in the Strøtfjord A Ballast Water System have, through a successful and complicated operation carried out in 1986, been changed and replaced by titanium, a new material in an offshore context, having better anti-corrosion properties and a much longer working life than other materials used in such pipes on the platform today. The paper describes the project which was finalized ahead of schedule and below budget. Physically, the operation took place in the Utility Shaft on the platform, and it had no impact on the production on board. Several departments of the Strøtfjord Division platform operator Mobil Exploration Norway Inc have been involved, as have contractor companies.

## Ice Problems

**079001 STUDY OF ICE-FORMATION PHENOMENA ON FREEZING OF FLOWING WATER IN A PIPE.** Ice-formation phenomena in a water pipe whose wall is kept at a uniform temperature lower than the freezing temperature of water are examined under the conditions of an unstable ice-water interface. The onset conditions for a step or smooth change in ice thickness occurring with flow transition from laminar to turbulent are found to be correlated with ice thickness at the contraction region of the ice band and are expressed as a function of a pipe Reynolds number  $Re_D$  and a cooling temperature ratio  $\theta$ . It is shown that the transient freezing process depends strongly on flow as well as temperature conditions and that the typical ice shapes at steady-state conditions can be classified on a  $\theta-Re_D$  coordinate system. Leak Detection See Also HEATING—District; PETROLEUM PIPELINES—Maintenance.

**079004 MATHEMATICAL MODEL FOR LEAK LOCATION IN PIPELINES.** In the present paper, a novel method for leak detection in pipelines is described. The method is based on a unidimensional flow analysis. The theoretical findings have been verified experimentally for two different hole geometries (circular and rectangular). The comparison set between theory and experiment confirms the physical realism of the mathematical model. The accuracy in calculating the leak position is estimated to be less than a few percent for the different hole geometries in question. (Author abstract) 6 refs.

**079005 SOME CONSIDERATION ON LEAKAGE DETECTION IN PIPELINES BY ACOUSTIC EMISSION.** It is emphasized in this paper that the flow density of a jet is an important factor which affects the AE signal levels. In the case of subsonic jet, AE signal level goes up as pressure in pipeline  $P_0$  increases regardless of shape and size of leakage hole. When a blocked jet occurs, the condition is very complex. Sometimes, but by no means always, a supersonic jet may be formed and AE signal level drops as  $P_0$  increases. AE signal excited by leaking jet is of continuous type and its frequency range is very wide. If the circumstance noise level is low, an accelerometer may be used to seek leakage. **079006 STUDY ON AUTONOMOUS PIPELINE MAINTENANCE ROBOT (3RD REPORT, STRUCTURE AND CONTROL OF MARK III AND OBSTACLE SENSING).** A new type of mobile robots with a looping movement mechanism in the lateral and circular direction of a pipeline is presented in this paper for pipeline maintenance operations. This robot has four degrees of freedom and more flexibility than the first and the second prototype robots, which have the wheel type of mobile mechanism for horizontally located pipelines. This robot can pass over obstacles such as flanges and also T-joint pipelines, which the previously reported robots can do, and furthermore has more pipeline maintenance adaptabilities such that the new robot can move along vertically located pipelines and that it can move to an adjacently located pipeline. Therefore, the control must be so complicated that the dual mode control is introduced by employing the coordinate transformation matrix. (Edited author abstract) In Japanese. 8 refs.

**079007 STUDY ON AUTONOMOUS PIPELINE MAINTENANCE ROBOT (4TH REPORT, JOINT CONTROL AND ITS TRAJECTORY GENERATION FOR MARK III).** The pipeline maintenance robot Mark III with the inch worm mechanism, presented in the 3rd report, can pass over obstacles on pipelines, such as flanges and T-joints and others. For this motion control, the joint control methods for Mark III, especially the optimal trajectory generation, are shown in this report. First, this robot system has the modified dual control mode, A and B, with the transfer matrices different from the previous method. The control mode is changed mutually when the basic arm grasping the pipe is changed. Second, the static joint torques are calculated to determine the desired transfer matrix, and a configuration which has the minimum joint torques is selected. Third, an optimal trajectory is generated by dynamic programming in order to control joints from the present angles to the desired angles. It has two criteria: joint torques and position errors. (Author abstract) In Japanese. 6 refs.

**079008 ON THE DYNAMIC RESPONSE OF FLUID-FILLED BURIED PIPELINES.** This paper presents a theoretical analysis of the axisymmetric steady state dynamic response of buried fluid-filled pipelines excited by seismic waves traveling in the surrounding infinite medium (soil). An infinite cylindrical shell model including the rotary inertia and shear deformation effects, has been used for the pipeline. Comparisons of the numerical results for a fluid-filled shell with those for an empty shell show that the presence of the fluid suppresses the response at some wavelengths but augments it at others. The overall response of the fluid-filled shell is observed to be quite different from that of the empty shells, and this difference is found to be more pronounced in softer soil conditions. (Author abstract) 12 refs.

**079009 POWERFUL IMPROVEMENT ON THE METHODOLOGY FOR SOLVING LARGE-SCALE PIPELINE NETWORKS.** Solving large-scale pipeline networks that give rise to huge sets of nonlinear algebraic equations is very time consuming and cannot be treated by conventional partitioning and tearing techniques, which tend to be very expensive in computer time. A new arrangement of the Hardy-Cross linearized system for the simulation of large-scale fluid network problems is presented, which dramatically improves the calculating procedure. Comparisons with other known procedures show a large reduction of the memory storage and computation time. The strategy makes a trade-off between the number of iterations and time required for each calculation resulting in an overall optimization of any physical system. Furthermore the method has been satisfactorily applied to the optimization of gas networks. (Edited author abstract) 16 refs.

## Measurements

**079010 STUDY ON POSITION MEASUREMENT METHOD OF A CONDUIT PIPELINE USING CUMULATING ATTITUDE.** A new position measurement method for conduit pipelines buried under public roads is proposed. In the new method, a piece of equipment consisting of two modules, a vehicle and a probe, move inside a pipeline. The probe measures the pipeline inclination and curvature radius. The pipelines position is calculated by cumulating the inclination and the attitude

obtained from the curvature radius measurement. Furthermore, position measurement accuracy is analyzed and evaluated with standard deviations of the inclination or curvature radius. The usefulness of this measurement method is confirmed through an experiment using a pipeline 80 mm in internal diameter and 40 m in length. The horizontal and vertical position measurement error is found to be smaller than 20 cm in the experiment. (Author abstract) 3 refs. In Japanese.

## Mechanical Properties

**079011 INCLUSION OF INTERMEDIATE PARTIAL CONSTRAINTS IN PIPING FLEXIBILITY ANALYSIS - A GENERAL APPROACH.** No method has yet been developed to unite intermediate partial constraints into the body of the equilibrium equation of the piping system. This paper describes a very general approach to piping flexibility analysis incorporating intermediate partial constraints. The method admits all types of intermediate partial constraints to be imposed simultaneously upon any node of the structure, such that some degrees of freedom of a node may be restrained by springs, some by external forces and some could be suppressed rigidly. The method, unlike all others, obtains the proper matrix equilibrium equation of the whole piping system. It is particularly suited for automatic computation. (Edited author abstract) 22 refs.

## Monitoring See Also PETROLEUM PIPELINES—Structural Analysis.

**079012 TROUBLE-SHOOTING TOOL.** Buried pipelines are constructed and operate in dynamic environments that make them vulnerable to a number of influences that are hazardous to their safe operation. The main operating principle of the C-Scan System is the remote measurement of the strength of a signal applied to the pipeline. The attenuation of signal strength is determined by measuring the strength of the C-Scan signal carried by the pipeline at any given survey point and comparing it with the current measured in the pipeline at some other survey point.

Sturgess, Robert W. (Pipeline Information Technologies Ltd, Calgary, Alberta, Can). *Pipeline Gas J* v 215 n 2 Feb 1988 p 18, 20-22.

**079013 INTEGRITY MONITORING FOR FLEXIBLE PIPES.** Flexible reinforced hoses to carry hydrocarbons and chemicals have been in operation for over 50 years. During the last war, the first steel reinforced subsea flexible hose was laid across the channel to transport fuel to support Allied landing operations in France. However, not until the 1970s because of progressions in oilfield developments and due to the need to reduce pipeline installation time and costs, were the first steel-reinforced flexible pipes actually placed in service. Flexible pipes should not be confused with and differ from flexible hoses, largely due to their method of construction, material, composition and reinforcement. Pipe construction is made up from alternating layers of polymeric (thermoplastic or elastomeric) materials, steels (both carbon and stainless), textiles (polyamide, Kevlar, polyethylene) and fabrics (for ozone, abrasion and fire resistance). The paper describes the two major types of construction of flexible pipe, bonded construction and unbonded construction. Discussed are designs and construction guidelines, modes and causes of pipe failure, and tools for pipe monitoring. 11 Refs.

**079016 NEW TRENDS IN CORROSION-RESISTANT OFF-SHORE PIPELINES.** The methods used for the production of clad steel pipe are roughly classified into assembling methods and casting methods. Of these, the following four methods are becoming popular. Seamless pipe of clad steel made by inserting alloy pipe into the carbon-steel pipe. The resulting pipe is hot-rolled or cold-worked. Welded pipe made from clad steel plate produced by explosion bonding or welding. Welded pipe made from plate produced by the hot-rolling of clad steel ingot. To make the ingot, molten carbon steel is poured into the mould in which the alloy plate has been placed. Carbon-steel pipe made by centrifugal casting or the like, after which alloy steel is cast inside it.

Anon. *Chromium Rev* n 7 Aug 1987 p 10-11.

**079017 OFFSHORE PIPELINES IN EUROPEAN MARITIME AREAS - THE YEARS AHEAD.** For effective pipelaying in these depths, where driver assistance is difficult, totally integrated installation systems will be required. The specific areas for deep water pipelaying in the European maritime areas are in the Norwegian Sea, Northern Atlantic Ocean between Rockall, the Faeroes and Scotland, in the Norwegian Trench and crossings of the Mediterranean. Effective pipelaying in deep water will require an integrated system. An integrated system consists of the totality of surface and subsea equipment needed to lay and connect a pipeline in deep water. The pipelay method is an important part of the overall pipeline design. Elements of the system required for deep water work are given. The author discusses pipelaying systems and their extension to deep water and factors relevant to the repair of deepwater pipelines.

Smith, C.J. *Mar Technol* v 17 n 2 May 1986 p 62-63.

**079018 AUTOMATED CHARTING FOR OFF-SHORE PIPELINES.** The latest TRAC IVB/CHART-IV automated processing and charting systems

allows the surveyor to choose a layout to suit his specific application from simple base sheets to customized multiple layouts with convenient defaults for rapid set-up. Complete intermixing of chart types is possible, including trackplots, bathymetric data, long sections, cross sections, profiles, key charts, information and logo panels. The system can produce any size of pipeline chart from A3 to AO with standard default sizes; non-standard sizes can be entered manually. Progressive recording of component sections of the chart to file eases editing and speeds duplication of the final sheet. Sheets may be replotted from file at a reduced overall size for inclusion in reports.

**079019 NORTH SEA PIPELAY PROJECTS WILL STRETCH SUPPLY BOAT MARKET.** On current trends, once plans being developed for major pipeline projects in the North Sea are put into effect in the early 1990s, there are unlikely to be sufficient specialized supply vessels to support the construction activity. The likely result will be a major increase in demand for conventional supply vessels during the pipelay operations, which could lead to shortages and day rate increases in the North Sea supply vessel market. This article reviews the project plans and discusses boat shortages and effects the construction activities.

Anon. *Mar Eng Rev* Jan 1988 p 24-25.

**079020 DESIGN AND OPERATIONAL CONSIDERATIONS FOR UNSUPPORTED OFFSHORE PIPELINE SPANS.** Design and operational considerations have been examined in determining the significance of unsupported offshore pipeline spans that may develop during pipeline installation or field operation. Allowable unsupported span lengths determined during design are generally based on strict code compliance and a design foundation encompassing the worst possible environmental and operational loads. During operation, however, unsupported spans develop beyond the allowable limits, perhaps as a result of various unforeseen local conditions. Applying original design criteria is likely to result in cost-prohibitive repair predictions, while lack of action may result in loss of production. Without the design code requirements of an existing or a proposed pipeline system being violated, realistically safe design can be approached through evaluation of the sensitivity of the key design parameters. (Edited author abstract) 8 refs.

**079022 APPRAISAL OF GLASS REINFORCED PLASTIC AS A PRESURE PIPELINE MATERIAL.** GRP pipe is a specialist pipe which can offer advantages in a small number of applications. However, when GRP is considered for pressure water mains, its limitations, risks and special characteristics must be evaluated. 'Stiff' GRP pipes are not equivalent to ductile iron and should not be considered as direct replacements. They are fragile, many times less stiff than ductile and require special embedments and close site control in order to ensure a reliable long term performance. The British Standard allows GRP pipes to be designed to very low, long term safety factors giving little reserve for the incidental loadings which inevitably occur in practice.

**Protection** See Also PIPE.

**079025 INCREASING THE PROTECTIVE CHARACTERISTICS OF BITUMINOUS COATINGS BY MODIFICATION WITH CORROSION INHIBITORS.** The influence of specific modifiers (standard products and waste products of large tonnage chemical and petrochemical production) on the anticorrosion properties of petroleum bituminous coatings is considered. The inhibiting modifiers were selected so that, in the composition of the bituminous coatings they did not have a significant detrimental effect on the strength and insulation properties. Quantitative data were obtained confirming the increased anticorrosion characteristics of coal tar and KKhO inhibitor modified bituminous coatings. The order of other inhibitors combining well with the bituminous base and strengthening its protective effect was also determined. The practical use of inhibiting modifiers makes it possible to substantially improve the technical and service parameters of the coatings and to prolong the service life of steel main oil and gas lines, water lines, and

pipe for irrigation and public systems. 9 refs.

## Protective Coatings

**079027 TAPE SYSTEMS FOR PIPELINE PROTECTION.** Pipeline tapes have been used for over 35 years and continue to be important and useful materials for protection against corrosion in a variety of environments. Pipelines, particularly those used underground, have special protection requirements, because of the susceptibility to mechanical damage during handling, lowering, and backfilling, and the corrosive nature of the soils. Pipeline tapes are one of the major options for achieving that protection, along with various other types of coatings. A disadvantage of the tapes is the vulnerability of the seam to ingress by water or other pollutants. Application of tapes is crucial, and improperly wound or poorly bonded tapes are susceptible to water penetration and corrosion. 8 refs.

**079028 DEVELOPMENT OF AN ULTRAVIOLET CURABLE PRIMER (UVC) SYSTEM FOR POLYETHYLENE COATED STEEL LINE PIPE.** Polyethylene extrusion coating pretreated with thermosetting epoxy primer has recently been applied for external pipeline protection. However, thermosetting primer takes more than a few minutes for curing, so it has been difficult to apply it in a high speed polyethylene coating line. To cope with this problem, we have studied and developed a new primer system, an 'Ultraviolet Curable (UVC) Primer System'. This newly developed UVC primer system has the following properties: 1) Quick curing, with a curing time of less than 5 sec. 2) High adhesion strength for both the steel surface and adhesive. 3) Excellent corrosion resistance. 4) Safe in the coating plant. Our new system has already been installed in the polyethylene coating line at the Wakayama Steel Works. (Author abstract) 5 refs.

## Reliability

**079030 CALCULATING THE RELIABILITY INDICATORS OF MAIN PIPE LINES BY A STATISTICAL MODELLING METHOD.** The finite element method is used to solve the problem of interaction when a large-diameter pipeline comes into contact with mounds of frost-swollen earth. The reliability indicators and empirical distributions of the functions of state of the pipelines are obtained using the theory of the elimination of random factors, the theory of the distribution of extreme random values, and methods of statistical modeling. It is shown that the widely used hypothesis on the normality of functions of state can lead to crude errors when the reliability levels of main pipelines are evaluated. (Author abstract) 7 refs.

Lobanov, E.V. *Sov Mach Sci* n 2 1987 p 78-83.

**079031 EVALUATING THE RELIABILITY OF PIPELINES AT HYPERCRITICAL DEFORMATION IN STATISTICALLY INHOMOGENEOUS WEAK SOILS.** A problem of hypercritical strain in trunk pipelines is solved with allowance for nonlinear bending and essentially nonlinear soil resistance. Reliability indicators are estimated by using a statistical-linearization technique and the theory of random-function spikes. It is shown that allowance for the nonlinear property of the soil reduces the failure rate to a fraction of that encountered with the classical Winkler base. (Author abstract) 3 refs.

Lobanov, E.V. *Sov Mach Sci* n 3 1987 p 44-49.

## Relocation

**079032 BORING REVOLUTION.** With many kilometres of old services to replace and new ones to lay, non-disruptive methods of installation offer attractive solutions, especially in urban environments. The preferred alternative which is rapidly penetrating the market is trenchless pipelaying. This is a term given to a wide variety of techniques and equipment which have the common characteristic of installing or renovating pipe without the need to trench. These trenchless pipelaying techniques include impact muling, pipe pushing, steerable moles, directional drilling, auger boring, microtunnelling and pipe jacking. The techniques of on-line replacement and in-situ renovation are now also included in this general term.

Thomson, James (Jason Consultants). *Int Constr* v 26 n 11 Nov 1987 p 80-82, 85, 87.

## Remote Control

**079033 SCADA FOR PIPELINE MONITORING AND CONTROL.** Supervisory control and data acquisition (SCADA) is a term used to describe the whole philosophy of electronic control and monitoring of plant processes, unlimited by distances, where a large amount of monitoring and few control points are used. Control center functions concentrate on all the information needed to monitor and control the pipeline - interactive graphic displays and reports, alarming and trending packages and event loggers with priorities given to pipeline safety sequencing.

**Removal** See WATER PIPELINES—Wear.

**Repair** See Also GAS PIPELINES—Leakage; INVENTORY CONTROL—Reliability; NATURAL GAS PIPELINES—Offshore; SEWERS—FAILURE; WATER PIPELINES—Leak Detection.

**079034 PIPELINE LINER ENABLES REPAIR WITHOUT DISRUPTION.** First used commercially in the United Kingdom in 1973, the Insituform process has

been developed to overcome the problems of failing pipes, be they sewers or industrial pipework, underground or just inaccessible. Insituform provides a new structural lining within the original pipe, greatly extending its life. A liner is manufactured of polyester felt to fit exactly the internal dimensions of the pipe to be lined, the outer layer of felt is coated with polyurethane to seal the felt tube. Resin is then mixed with a catalyst and fed into the end of the soft felt liner, the resin totally impregnates the felt. The liner is then taken to site and turned inside out into the defective pipe. This is known as the inversion.

## Reviews

**079035 PIPELINE INFRASTRUCTURE, PROCEEDINGS.** This conference proceedings contains 49 papers, which concern pipeline infrastructure topics. The papers cover innovative pipeline design, condition monitoring, soil-pipe interaction, inspection, maintenance, and rehabilitation. The entire spectrum of pipeline fluid systems is discussed. This includes oil, gas, water, sewer, and steam piping systems. Seismic design is also addressed. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11596 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**River Crossings** See NATURAL GAS PIPELINES—Construction.

**Saarland, Federal Republic of Germany** See HEATING—District.

**Shock Waves** See Also HYDRAULICS—Shock Waves.

**079036 EFFECT OF A GROUND SHOCK WAVE ON AN UNDERGROUND PIPELINE.** Underground pipelines may be affected by seismic or explosive waves spreading in the ground. In a previous paper stationary problem was investigated where a seismic wave acted on an infinite pipeline modeled by an elastic rod and interacting through the surface with the surrounding ground. The present paper analyzes nonstationary motion of a semiinfinite pipeline - a rod affected by a stepped shock wave spreading in the ground. (Edited author abstract) 2 refs.

## Simulation

**079037 PIPELINE SIMULATION INTEREST GROUP AGENDA, PSIG EIGHTEENTH ANNUAL MEETING.** This conference contains 9 papers. The subject matter is primarily concerned with monitoring, simulation and evaluation of transients associated with flow in pipelines. Some specific topics are optimal gas pipeline design, leak detection in pipeline networks, optimization of a city water distribution system, application of transient analysis to a pipeline system, transient flow simulation in natural gas pipelines, real time simulation on a gas transmission system, real time simulation of a batched pipeline network, real-time pipeline leak monitors, and composition tracking for pipeline networks. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11285 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

## Stability

**079038 STUDIES ON THE STABILITY OF PIPES CONVEYING FLUID: (THE COMBINED EFFECT OF A SPRING SUPPORT AND A LUMPED MASS).** The present paper deals with the combined effect of a spring support and a lumped mass on the stability of a tubular cantilever conveying fluid. The support and the mass are assumed to be attached to the cantilever at the same location. The validity of Galerkin's 8 term approximation is discussed from the viewpoint of predominant eigenmodes in critical flutter configurations. It is shown that for particular combinations of spring stiffness and lumped mass there exists an instability region which juts out from the main flutter domain. Both theory and experiment confirm that the instability in the region is of mild flutter type, not violent. (Author abstract) In Japanese. 11 refs.

**079039 INSTABILITY OF BURIED FLEXIBLE PIPE - PART 1.** This paper reviews various instability or buckling theories, models and tests, and proposes a method for predicting and preventing pipe buckling that is based on proven theory and consistent with experience. Many of its aspects depart substantially from the usual approaches. The paper also includes supporting data. (Author abstract).

Prevost, Robert C.; Kiewnow, Kenneth K. *Pipes Pipelines Int* v 33 n 3 May-Jun 1988 p 26-33.

**079040 INSTABILITY OF BURIED FLEXIBLE PIPE - PART 2.** This is the second part of a major investigation into the design of buried flexible pipe. In Part I the authors examined the theory of two basic instabilities, and discussed the experimental evidence that exists to date. Part 2 starts with the continuing review of the metal corrugated culvert. (Author abstract). 15 Refs.

**Stresses** See Also BELLOWS—Stresses; PETROLEUM PIPELINES—Accident Prevention; PIPELINES, SUBMARINE—Laying.

**079041 NOTCH DUCTILITY REQUIREMENTS OF LINE PIPES FOR ARRESTING PROPAGATING SHEAR FRACTURE.** Full-scale burst tests were carried out on X70 line pipes, 48 in. o.d.  $\times$  0.720 in. w. t., with air and rich and natural gas as the pressurizing gases. The experimental results indicated that very high notch ductilities of pipes are required for arresting propagating shear fracture especially in the case of the rich natural gas. From theoretical investigations a method was developed which enabled the prediction of the required notch ductilities of line pipes with regard to the type of gas, design stress and acceptable fracture length. (Author abstract) 6 refs.

**079042 DETERMINATION OF STRESS FIELD IN BURIED THIN PIPELINES RESULTING FROM GROUND SUBSIDENCE DUE TO LONGWALL MINING.** When a pipeline is laid across a subsidence-prone area as a result of underground longwall mining, it is not always necessary to take measures to protect the full length of the pipe. In this paper, some guidelines are proposed for partial or full protection in order to prevent possible damage to the pipeline. The techniques of determining the magnitudes and locations of the maximum tensile and compressive stresses on the pipeline are developed. Based on the assumptions that the pipelines are thin and that the ground subsidence can be predicted by the probability function integration method. Two computer programs were developed to assist in the determination of the optimal control parameters of a

subsidence profile and evaluate the stresses on the pipeline. (Author abstract) 4 refs.

Peng, S.S. (West Virginia Univ, Morgantown, WV, USA); Luo, Y. *Min Sci Technol* v 6 n 2 Jan 1988 p 205-216.

**079043 ENGINEERING DESIGN METHOD CAN PREDICT TAPE WRINKLES.** Buried line pipe wrapped with tape, is subjected to shearing forces induced by the surrounding soil which can result in tape wrinkling. The authors propose an engineering design method to predict the time of wrinkling and describe the actions to be taken to avoid this problem. The proposed design method allows the following properties as variables: soil density, soil internal friction, burial depth, pipe radius, soil/coating friction coefficient, coating/soil adhesion coefficient, tape thickness, film elastic modulus, number and size of wrinkles. 3 refs.

**Structural Analysis** See Also RINGS—Structural Analysis.

**079044 HIGH LEVEL DYNAMIC TESTING AND ANALYTICAL CORRELATIONS FOR A SMALL BORE PIPING SYSTEM.** High-level dynamic testing of a prototype insulated small bore diameter pipe system is described. The pipe system was supported by a minimum number of supports, with several combinations of supports and support locations tested. Load input consisted of a dynamic multifrequency time history and sinusoidal loading at increasing acceleration levels until gross deformation of the system occurred. Very high level pipe damping was exhibited when plastic response occurred. Post-test analyses were performed to assess the structural loading and response of the pipe system under the dynamic load input. Several elastic and elasto-plastic analysis failure prediction methods were used, along with simplified inelastic analysis. (Author abstract). 8 Refs.

## Substrates

**079045 EFFECTS OF LEE-WAKE ON SCOUR BELOW PIPELINES IN CURRENT.** The results of an investigation of the effect of lee-wake on scour below pipelines in currents are reviewed. The subject is investigated both experimentally and numerically. The experiments show that the scour downstream of the pipe is apparently governed by the action of an organized wake flow, which is an agglomeration of large-scale vortices which are shed from the pipe and steadily convected downstream. The experimental results lead to a clear understanding of the effect of lee-wake on the scour phenomenon. In the numerical part of the study the so-called cloud-in-cell method is employed to predict the flow. The results appear to reveal almost all the features of the organized wake flow shown by the experiments. The theoretical calculations demonstrate that the time average bed shear stress is not a suitable parameter to work with in mathematical-model studies of lee-wake scour. (Author abstract). 10 Refs.

**Thermal Effects** See NATURAL GAS PIPELINES—Testing.

## Transients

**079047 INVESTIGATION OF NON-STATIONARY REGIMES OF THE MAIN PIPELINE.** A mathematical model describing thermohydraulic processes in main pipelines is presented in a form sufficiently complete for real tubing study. Originating from the difference in the thermal and hydraulic phenomena in the pipeline, the method of non-stationary thermohydraulic process division into two types of problems is suggested allowing a considerable simplification of the non-stationary oil flow regime study. The temperature dependence consideration of the friction factor is shown. Individual member effects in the model equations, taking into consideration different oil flow conditions, was estimated. The paper describes solution methods of thermal and hydraulic problems. (Edited author abstract) 2 refs.

**Trenching** See Also NATURAL GAS PIPELINES—Laying; PIPE—Supports.

**079048 INDUCED TRENCH METHOD - A CRITICAL REVIEW AND CASE HISTORY.** The "induced trench" method for buried pipe protection is reviewed. By installing a zone of relatively compressible material within the backfill above a pipe, soil arching is induced. This has the effect of reducing the vertical earth load on the pipe, permitting the pipe to be buried at a greater depth than would otherwise be tolerable. In many circumstances, the method can offer significant economic benefits over alternatives. The theory on which currently available design methods are based is somewhat outdated and fails to address many factors that affect performance. For a recent project in Calgary, Alberta, a nonlinear finite element simulation was carried out to optimize the design. Performance during and after installation was monitored. Vertical pressures on the pipe were significantly less than those predicted by conventional theory. There is a need for the development of a more rational approach that is suitable for routine design. (Edited author abstract). 18 Refs.

**Vibrations** See Also FLOW OF FLUIDS—Pipes; SOILS—Underwater.

**079049 DYNAMICS OF BURIED PIPES IN BACK-FILLED TRENCH.** Dynamic response of pipelines lying in a back-filled trench in a semi-infinite medium is investigated. The pipelines are modeled as circular cylindrical shells of small thickness. The problems considered are the ones of plane strain, in which it is assumed that the waves are propagating perpendicular to the pipe-axes. Since no exact solution is obtainable for the problems considered here, a numerical technique that combines the finite element method with multipolar representation of the scattered field is used. Numerical results are presented for the normal displacements, as well as the hoop stress in the pipewall either in the presence or absence of another pipe lying nearby. (Author abstract) 11 refs.

**079050 LATERAL VIBRATION OF A CANTILEVERED FLEXIBLE PIPE CONVEYING FLUID (A**

**HORIZONTAL EXCITATION AT THE UPPER END OF THE VERTICAL PIPE).** The lateral vibration of a flexible pipe, which is hung vertically and conveys fluid is examined theoretically and experimentally for the case where the upper end of the pipe is periodically excited. Using nonlinear coupled equations with respect to axial fluid velocity and lateral deflection of the pipe, the complex equation governing the amplitude and the frequency of the lateral vibration is derived, near the critical fluid velocity above which the lateral vibration is self-excited. Furthermore, the experiment was conducted with the flexible pipe model conveying water. The heat phenomena in the lateral vibration of the pipe, as predicted by the theory, was observed slightly above the critical fluid velocity. (Author abstract) In Japanese. 7 refs.

**Welding** See Also PIPELINES, STEEL—Corrosion Resistance.

**079052 EFFECT OF MODIFYING ADDITIONS ON THE SERVICE RELIABILITY OF WELDED JOINTS IN PIPELINES.** Results are presented of examining the separate and combined effects of microadditions of cerium and zirconium, as well as together with cobalt on the structure and toughness of deposited metal based on the manganese-nickel-molybdenum electrode alloying system. The experiments were carried out on VSt3sp steel. The results show that cold strength of deposited metal in the given alloying system can be increased by complex introduction into the composition of the electrode coating of cobalt, CO<sub>2</sub> and an Si-Zr master alloy. The beneficial effect resulting from the introduction of these components is obtained if the deposited metal contains 0.10-0.15%Co, <0.010%Ce, <0.006%Zr. 8 refs.

Rakhmanov, A.S. *Weld Prod* v 33 n 11 Nov 1986 p 22-24.

**079053 HEAT HARDENING OF ELECTRIC-RESISTANCE WELDED LARGE DIAMETER LINE PIPE.** The commercial production of heat hardened 820, 1020 and 1220 mm electric-welded thin-walled K-60 pipes from steel grades 17G2SF and 17GIS for 5.5 MPa gas and oil lines has been outlined. The mechanical properties of pilot batches of heat hardened 1420 x 14 mm 16GFR pipes and 1420 x 15.1 mm 17GIS-U pipes in strength categories K-70 and K-65 for 7.5 MPa Arctic lines have been analyzed. It has been shown that use of optimal heat hardening conditions results in property levels which meet the specification requirements. (Author abstract) 3 refs.

Pozdnyakov, L.G.; Atamanenko, V.A.; Pichurin, I.I. *Sov Mater Sci Rev* v 1 n 1 1987 p 109-113.

**079054 PERFORMANCE OF HEAT HARDENED SPIRAL-WELDED LINE PIPE.** The production of heat hardened spiral-welded pipes at the Volzhskiy pipe plant has been described. The heat hardening process has been found to be highly effective in terms of improved life, better resistance to brittle fracture and to ductile crack propagation, as well as higher design strength of pipes. Trends in the use of heat hardened pipes have been considered. (Author abstract)

*Mater Sci Rev* v 1 n 1 1987 p 115-117.

**079055 LONGITUDINAL WELDING OF PIPES WITH HIGH-FREQUENCY GENERATORS.** Electronics is indispensable for the longitudinal welding of pipes with high-frequency generators. Rising quality requirements and larger dimensions are leading of necessity to greater high-frequency outputs. Using a precise and quickly adjustable high-frequency output combined with a temperature control facility, it was possible to automate the welding operation of a second high-frequency generator with a high terminal output of 1100 kW. Pipes to API standard can also be welded with this generator. (Author abstract)

Wiehn, Peter. *Strips Sheets Tubes* v 4 n 2 Dec 1987 p 25-27.

**079056 MAG-ORBITALSCHWEISSEN IM ANLAGENBAU UND BAU ERDVERLEGETER ROHRLEITUNGEN.** [MAG Orbital Welding in Plant Construction and in the Installation of Earth-laid Pipelines]. The author compares the MAG orbital welding and drop joint welding techniques. He describes the method, the equipment and the power sources and explains the personnel requirements, additional materials, the course of the work and the welding parameters. Finally, he reports on his experiences in the construction of district heat pipelines in Copenhagen and Berlin. The new MAG orbital welding technology is currently only a supplement to drop joint welding, because its economy is dependent on the pipe dimensions and the thickness of the pipe walls. The MAG orbital method has been used in pipeline construction for some time in countries where climatic conditions are different from those prevailing in Europe. 3 refs. In German.

Vietz, Eginhard (E. Vietz Schweisstechnik, GmbH, Hanover, West Ger). *Fernwaerme Int* v 17 n 2 Mar-Apr 1988 p 72-77.

**079057 SHORTAGE OF SKILLS, LABOUR PUTS EMPHASIS ON MACHINERY.** The manual metal arc (MMA) welding process originated in the 1920s and continues to be the most widely used joining technique for pipeline construction on land. The fabrication procedure has hardly changed. The paper discusses the developments of welding processes in on-shore pipeline construction. These processes have not changed much in 60 years, but off-shore developments are pointing the way to higher welding speeds and improved quality, according to The Welding Institute based in Cambridge.

Anon. *Gas World* Jun 1988 p 14,16.

**079058 EFFECTS OF FLOWING PRODUCT ON LINE WELDABILITY.** Experiments on a flowing liquid-propane pipeline have established welding parameters for repair and hot-tap welding on pressurized pipelines. The welding experiments on a liquid-propane pipeline in service confirmed the influence of pipe-wall thickness (W.T.), heat input, fluid-flow velocity, and material carbon equivalent on safety and pipeline integrity. Data reported follow an earlier article which describes the computer models of the heat-transfer process during welding. In this article results of a series of hot-tap welding experiments are analyzed. 7 Refs.

## PIPELINES, CAST IRON

### Corrosion

**079059 DETERIORATION DIAGNOSIS IN IRON CONDUIT.** This paper describes a technique for diagnosing deterioration in iron conduits. The outer surface of an underground iron conduit corrodes to contact the soil. A non-contact measurement technique is developed for determining corrosion in iron conduits thinner than 4 mm by frequency-domain signal processing to an electromagnetic ultrasonic technique. Speedy diagnostic equipment using these techniques has been developed, while features

a new compact sensor which can be extended into conduits. (Author abstract) 11 refs.

Sudoh, Yoshikazu (NTT, Jpn); Honjoh, Katsuhiko; Masuda, Jun-ichi. *Rev Electr Commun Lab (Tokyo)* v 35 n 6 Nov 1987 p 701-706.

## PIPELINES, CONCRETE

### Concrete Construction

**079060 TECHNOLOGY OF CASTING PRECAST PIPELINE ELEMENTS OF THE KAISIADORYS PUMPED-STORAGE STATION.** The Soviet construction industry widely used superplasticizers—technological additives to the concrete mix having properties of brief effective dilution of the concrete mix for a period of its placement of 1.5-2.0 h from the time of mixing and not affecting the structural and deformation properties of the concrete, since it does not enter into chemical reactions occurring in the concrete during its hardening. Among such effective diluents of a concrete mix are the superplasticizer S-3 (technical specifications TU 6-15-623-80) and —Dofen— (TU 6-188-81) developed for the manufacture of precast reinforced concrete at casting yards or factories. The use of the cast concrete mix with a superplasticizer for concreting structures is technically expedient and economically effective. Such structures are: bored piles, heavily reinforced structures, plain cast, those cast in reinforcement panels, precast pipelines, etc.

Ospov, A. D.; Yudina, N. V.; Yakubonis, R. A.; Velanishkis, I. M.; Lyapin, O. B.; Slozhenikin, V. V. *Hydrotech Constr* v 21 n 7 Jul 1987 p 436-441.

Inspection See HEATING—Pipelines.

### Laying

**079061 REINFORCED CONCRETE PIPES FOR PIPEJACKING.** The impact of loading on the still young construction method of pipe-jacking is evident. As can be seen, different load induction areas can occur and act upon the pipe which greatly affect the stress and strain it is subjected to. Proceeding from the Kolosov principle on stress functions a generally applicable relation on effecton earth loads can be derived for calculating the earth load development. Suggestions on the background and further possible applications of the theory complete the observation. The bibliography contains a selection of the applied theoretical principles and information on existing literature on pipe-jacking. (Edited author abstract) In German and English. 23 refs.

Vogler, Georg. *Betonwerk Fertigteil Tech* v 53 n 12 Dec 1987 p 851-856.

### Performance

**079062 ANALYSIS OF REINFORCED CONCRETE-PIPE PERFORMANCE DATA.** Concrete pipes may be subject to deterioration from various conditions, including freeze-thaw weathering, acid corrosion, sulfate disruption, velocity abrasion of the concrete, and chloride corrosion of the reinforcing steel. The service life of reinforced concrete pipe thus varies significantly. Also, there are few detailed studies on concrete-pipe durability. Furthermore, analyses of the same data by different researchers have produced equations predicting dramatically different service lives. The results of two researchers' analyses in the form of service-life equations, based on the most complete data set available, are presented and analyzed. While neither of their service-life equations can be judged a good model of concrete-pipe deterioration, one is shown to better model actual field performance. This analysis also suggests the direction for future data-collection efforts. (Edited author abstract). 6 Refs.

Potter, John C. (US Army Engineers, Vicksburg, MS, USA). *J Transp Eng* v 114 n 5 Sep 1988 p 530-538.

### Standards

**079063 MANHOLE SYSTEMS: A DESCRIPTION OF PREFABRICATED MANHOLES FOR GRAVITY-FLOW PIPELINES ESPECIALLY PRODUCED IN SCANDINAVIA.** Demands on the design of manhole bases are being introduced in norms and standards. The latest Danish Standard of concrete pipes thus contain detailed demands on geometrical design. In order that a manhole system can form a natural part of a drainage and sewerage system it is necessary to have a well-developed range of fittings such as short-length pipes, double-spigot pipes, reducing pipes, bends and junctions. The manhole base itself must not be heavier than absolutely necessary to avoid using extra heavy lifting gear for the work. The lower weight limit is, however, decided by production considerations. There are both advantages and disadvantages connected with the use of prefabricated manholes. In conclusion, some of these are mentioned in this article. In German and English.

Ingwersen, John B. *Betonwerk Fertigteil Tech* v 53 n 9 Sep 1987 p 627-631.

### Trenching

**079064 NEW DUTCH METHOD FOR THE CALCULATION OF LOADS ON BURIED PIPES AND THEIR ANALYSIS.** The report on which this article is based has been published by the Netherlands Centre for Research and Development in the Field of Concrete (CUR), Gouda, in collaboration with the Delft University of Technology's Institute for Soil Mechanics and the consulting engineers' firm of DHV, Amersfoort. We believe that with CUR 122 we have split up an overall problem into manageable parts. Many of the assumptions made are controversial, but with the overview that we now have we can study each detail and, if necessary, improve it. We are convinced that this will lead to further improvement in the analysis of buried pipes. It emerges that, in comparison with the other pipe materials considered here, concrete—the construction material par excellence of this century—offers the most reliable solution. (Edited author abstract) In German and English.

Geene, W.F. *Betonwerk Fertigteil Tech* v 53 n 9 Sep 1987 p 621-626.

## PIPELINES, STEEL

Cathodic Protection See Also NATURAL GAS PIPELINES—Leak Detection.

**079065 MAGNESIUM ANODE UTILIZATION.** Magnesium is one of the most effective and economical metals for underground sacrificial anodes because of its strong anodic potential and high electrochemical equivalent. The most practical and economical method of providing cathodic protection for coated pipelines is a system of anodes distributed along the length of the pipeline. Installations vary from one anode per mile to groups of three or four anodes with a spacing between groups of 2 to 5 miles.

Anon (Pipeline & Gas Journal, Dallas, TX, USA). *Pipeline Gas J* v 215 n 2 Feb 1988 p 23-24, 26.

**079066 HYDROGEN GAS EVOLUTION FROM CATHODICALLY PROTECTED PIPELINE STEEL SURFACES EXPOSED TO CHLORINE-SULFATE SOLUTIONS.** An experimental study of the conditions for hydrogen discharge and the associated pH changes in chloride-sulfate solutions was conducted for different pipeline steel surface conditions. The highest potential for gas discharge is shown to be in reasonable agreement with the value quoted in the literature ( $-1.15 \text{ V Cu-CuSO}_4$ ) for pipeline surfaces exposed to other solutions, although somewhat higher potentials can prevail if the surface has previously been exposed to lower potentials. The extent of gas evolution is essentially determined by the magnitude of the current flowing at the surface, which varies with the polarization characteristics of different surfaces and solution compositions. The associated pH value increases in the solution, a matter of considerable importance in

relation to coating disbondment or the generation of a potent stress corrosion cracking (SCC) environment, are dependent upon solution composition as well as the amount of gas evolved. (Edited author abstract). 5 Refs.

Parkins, R.N. (University of Newcastle upon Tyne, Newcastle upon Tyne, Engl); Markworth, A.J.; Holbrook, J.H. *Corrosion (Houston)* v 44 n 8 Aug 1988 p 572-580.

### Cavitation Corrosion

**079067 CORROSION-EROSION CONDITION OF THE STEEL TUBES OF NO. 4 LOW-PRESSURE FEEDHEATER DURING A LONG PERIOD OF OPERATION WITH OXYGEN WATER TREATMENT.** A mandatory condition for changing over supercritical power-generating units to oxygen water treatment is that there must be no elements of plant fabricated from copper-containing alloys after the condensate polishing plant, so as to prevent entrainment of copper compounds into the turbine with subsequent build up in the flow section of the high-pressure cylinder. The experience which has been gained over 13 years with stainless steel tubes in 1.p feedheaters with oxygen treatment of water has shown their high operational reliability. Industrial testing under oxygen water treatment conditions of tubes of 20K steel of diameter 16 mm and with wall thickness of 1.5 mm was started in February 1979 on No. 4 1.p. feedheater of the No. 4 300 MW generating unit at Konakovo CP Station. During a six-year period of testing, i.e. from 1979 to March 1985, No. 4 unit worked for 45 500 h, 85% of the calendar time. The mean annual operational characteristics with oxygen water treatment during these years were below the Standard levels, iron concentration in the feedwater and live steam varying within bounds of 5-7  $\mu\text{g/kg}$ . 5 refs.

### Construction

**079068 EXPERIENCE IN THE CONSTRUCTION AND OPERATION OF STEEL PRESSURE PIPELINES OF HYDROPOWER DEVELOPMENTS.** The experience of designing, constructing, and operating high-head hydro developments, primarily of a power purpose, indicates considerable success of Soviet pipeline construction. With respect to the achieved indices of HD and HD<sup>2</sup> (H, head; D, pipe diameter) Soviet pipelines are not inferior to the largest foreign representatives. The construction of pipelines at the Nurek, Charvak, Krasnoyarsk, Shamba, Sayano-Shushenskoe, and other hydroelectric stations and the Zagorsk and Kaisiadorys pumped-storage stations was accompanied by the creation of new designs and technologies concerning the construction of branches, the use of effective high-strength steels, mechanization of assembly and welding operations on slopes and in tunnels in combination with drilling and grouting operations, high-productivity technology of manufacturing reinforcement cages and links, and improvement of inspection methods. 4 refs.

Freishtat, A.R. *Hydrotech Constr* v 21 n 3 Mar 1987 p 123-134.

Corrosion See Also PIPELINES—Offshore; SLURRY PIPELINES—Erosion; STEEL CORROSION—Underground.

**079069 USE OF LATERAL OR SIDE-DRAIN POTENTIALS TO INDICATE EARTH CURRENT DIRECTION ON BARE PIPELINES.** Lateral or side-drain potentials measured over and/or transverse to a buried pipe have been used to assess hot spots (current discharge areas) on unprotected pipe. In some cases, side-drain potentials have been used to indicate the direction of cathodic protection current criterion recommended in NACE Standard RP0169-83. Research has

shown by computer simulation and field measurements that the current (direction and magnitude) at the pipe is linearly related to the ground level transverse potential gradient. The lateral distance of the reference electrode(s) is important for correct interpretation of current direction, particularly with distributed-anode protection systems. There are minimum values for the transverse potential gradient that must be exceeded to have confidence that the net current on the pipe is all cathodic. (Author abstract) 2 refs.

**079070 APPLICATION OF THE SLOW STRAIN RATE TEST METHOD FOR THE DEVELOPMENT OF LINEPIPE STEELS RESISTANT TO SULPHIDE STRESS CRACKING.** High grade linepipe steels may be sensitive to hydrogen embrittlement in sour environments. This sensitivity may appear under conditions of sulphide stress cracking (SSC) and even in the absence of applied stress. Several metallurgical parameters play a role in this susceptibility. In this study, only SSC is considered. The slow strain rate technique (SSRT) is shown to complement the constant load test method (NACE TM01-77) in pointing to the influence of some metallurgical parameters and to differentiate more accurately the behaviour of some high grade linepipe steels. The influence of specimen orientation with respect to rolling direction, of rolling conditions and segregation leading to the formation of hard bands on cooling is particularly considered. The influence of experimental conditions on the SSRT results is discussed. The results obtained by these two test methods are in agreement, although SSRT seems more accurate and selective. The choice of sensitivity criteria is discussed and the criterion best describing the material behaviour in the corrosive environment is the normalized uniform elongation. This criterion represents the loss of ductility of the steel due to hydrogen embrittlement. (Author abstract) 35 refs.

Margot-Marette, H. (IRSID, St. Germain-en-Laye, Fr); Bardou, G.; Charbonnier, J.C. *Corros Sci* v 27 n 10-11 1987 p 1009-1026.

**079071 CORROSION AND HYDROGEN-INDUCED CRACKING OF PIPELINE STEEL IN MOIST TRIETHYLENE GLYCOL DILUTED WITH LIQUID HYDROGEN SULFIDE.** The corrosion of flowline steel in mixtures of liquid  $H_2S$  and triethylene glycol (TEG) at 3°C increases with increasing water content. With 1% of water in the total liquid no corrosion occurs even in the presence of elemental sulfur and chlorides. With 2% of water in the total liquid corrosion occurs at and above 5°C. At 3°C contact of steel with elemental sulfur considerably enhances the corrosion rate, but not the susceptibility to hydrogen-induced cracking (HIC) which is in contrast to sour systems without liquid  $H_2S$  at or above 10°C. The presence of NaCl stimulates HIC. Increasing the temperature from 3 to 7°C significantly enhances the corrosion rate. Additional  $CO_2$  yields no extra effects. (Author abstract) 2 refs.

Schmitt, Guenter (Ruhr-Univ Bochum, West Ger); Sobbe, Ludger; Bruckhoff, Wolfgang. *Corros Sci* v 27 n 10-11 1987, Hydrogen Sulphide Induced Environ Sensitive Fract of Steels, Sel Proc from the Int Conf, Amsterdam, Neth, Sep 10-12 1986 p 1071-1076.

**079072 HYDROGEN PERMEATION AND HYDROGEN-INDUCED CRACKING BEHAVIOUR OF LINEPIPE IN DYNAMIC FULL SCALE TESTS.** Full scale simulation tests have been conducted on large diameter linepipes of API grade from X42 to X65 with various hydrogen-induced cracking (HIC) susceptibilities. The pipes are tested under pressure of 72% SMYS with circulating dynamic natural gas including 0.2 or 1.5 MPa of  $H_2S$  partial pressure and 3.0 MPa of  $CO_2$  partial pressure brine present at the bottom of the pipes. The influence of  $H_2S$  partial pressure, gas velocity and chemical composition of the pipes on the hydrogen permeation behavior and HIC occurrence are studied by electrochemical measurement, ultrasonic test and metallographic

observation. The relationship between the full scale tests and laboratory tests are also discussed. (Author abstract) 19 refs.

Hyodo, T. (Iron & Steel Inst of Japan, Tokyo, Jpn); Iino, M.; Ikeda, A.; Kimura, M.; Shimizu, M. *Corros Sci* v 27 n 10-11 1987 p 1077-1098.

**079073 USE OF FRACTURE MECHANICS IN SULPHIDE STRESS CRACKING TESTING.** The traditional test method for sulphide stress cracking, i.e. the NACE TM 0177, provides a frame of conformity and gives an index of susceptibility of the tested steels. It gives, however, very little information of direct engineering use. By the use of fracture mechanics testing it is possible to obtain more quantitative data for use in predictive life analysis, etc. The step-loading test method has been shown to produce reliable test results of  $K_{ISCC}$  for sulphide-induced hydrogen crack initiation in a relatively short test time and with a minimum number of test specimens. (Author abstract) 5 refs.

## Corrosion Resistance

**079074 STAINLESS STEEL GAINS GROUND ON CORROSION.** In the continued effort to enhance corrosion resistance, such elements as nickel, molybdenum, and titanium have been added to today's stainless steels. The results have been alloys that exhibit tremendous strength, along with greatly increased corrosion resistance. Of these complex stainless steel superalloys, the 300 series appears to demonstrate these qualities best. And it is from two specific products within the 300 series, Type 301 and Type 304, that most stainless steel pipe, couplings and other fittings are made. In the results of tests conducted by the National Bureau of Standards there is evidence to show that, in its current formulation containing 18 percent chromium and 8 percent nickel, Type 304 is superior to Type 301 in corrosion resistance. This is especially true where underground, in-soil applications are concerned.

Tarara, James (Clamp-All Corp, Haverhill, MA, USA). *Water Eng Manage* v 135 n 1 Jan 1988 p 33-34.

**079075 RESISTANCE OF WELDED LINEPIPES TO SULFIDE STRESS CRACKING.** The SSC behavior of welded linepipes has been studied using tensile SSC tests (NACE TM-01-77), full thickness SSC tests, and full scale SSC tests. The results have indicated that homogenization of microstructures, which can be attained by reducing a carbon content to <0.05% or by quenching and tempering, improves the resistance to SSC. Most specimens from SAW welds fail at the heat affected zone (HAZ), regardless of differences in the microstructures of the parent materials, and they show nearly the same level of  $\sigma_{th}/\sigma_y$  ratio. Detailed metallographic examinations have been performed in order to understand the influences of steel chemistries and heat inputs in welding on the SSC resistance of the HAZ. Relations between the results of the laboratory tests and full scale tests are also discussed. (Author abstract) 11 refs.

## Failure

**079076 UNSTABLE FRACTURE TEST OF CIRCUMFERENTIALLY CRACKED TYPE 304 STAINLESS STEEL PIPES.** The authors are performing an unstable fracture test of circumferentially cracked pipes in order to investigate the possibility of mitigating the conservative assumption of guillotine break in lightwater reactor pressure boundary piping. The tests were performed at 285°C and at 6.86 MPa using type 304 stainless steel pipes of 165.2 mm in diameter and 11.0 mm in thickness. It is concluded that the predicted fracture load by the net-section-stress approach is conservative in a limited range of crack dimensions. (Author abstract) 9

## Lining

**079077 ABRASION RESISTANT PRODUCTS AND LUBRICATION.** The china clay has always been extracted by washing it out of the kaolinized granite with water. It is difficult to imagine a more abrasive mixture than mica, quartz sand and granite stone and this problem is exacerbated by the large volumes involved. The engineering and equipment arm of ECC International Ltd, now known as Charlestown Engineering, commenced a detailed search for a suitable pipe lining material which would give the necessary life. As a direct result of the successful test program it was decided that the pipeline would be lined with a polyurethane lining. The first pipes for this micaceous residue system were laid and commissioned in 1972. To date, the promised performance of the early test work on polyurethanes has more than lived up to expectations. In addition to its anti-abrasion properties, polyurethane has excellent tolerance to a wide range of corrosive materials, making it an ideal solution to wear problems in most industries.

## Manufacture

**079078 MODERN BRITISH STEEL SELLS QUALITY PIPELINE TO THE WORLD.** British Steel's Tubes Division operates modern tube-making mills at Corby in Northamptonshire, in the north-east, in Scotland and in the East Midlands to supply world markets with high-quality linepipe for gas transmission. The processes used to produce to American Petroleum Institute (API) standard are by electric welded and submerged arc welded pipe methods, and by seamless pipe manufacture. Electric welded linepipe, manufactured by the division's Welded Business - the Tubemasters - is increasingly being accepted for high-integrity applications such as linepipe. The paper gives a review of the revitalised corporation which, after spending millions on modernising and restructuring its plants, is finding a ready home and export market for its gas transmission products.

Anon. *Gas World* Jun 1988 p 12-13.

Pressure Effects See PRESSURE VESSELS—Stresses.

## Protective Coatings

**079079 SHORTER FBE-COATING TESTS PASS TRIALS.** Evaluations by NOVA Corp. of Alberta have shown that 24-hr cathodic-disbondment tests of fusion-bonded epoxy pipeline coatings will indicate coating adhesion as reliably as the industry-standard 48-hr tests. These results imply significant cost savings during pipe-laying operations when these routine tests indicate the need for recoating a section of pipe. 3 Refs.

Quality Control See STEEL TESTING—Fracture.

## Testing

**079080 ROTATING-DRUM RIG FOR TESTING PIPELINE ANOMALY DETECTORS UNDER SIMULATED LINE PRESSURE.** A rig for testing magnetic flux leakage detectors for pipeline monitoring applications is described. It uses short sections of line pipe supported and driven by two pairs of truck wheels. Test detectors are pressed against the outside of the pipe. Detector design, including the use of neodymium-iron-boron magnets and finite-element flux leakage calculations, is described. Experimental results are presented and signal processing and noise are discussed. A hydraulically pressurized

sealed pipe has been used to investigate the effects of line-pressure stress on detector performance. (Author abstract) 5 refs.

**Welding** See Also GAS PIPELINES—Welding; NATURAL GAS PIPELINES—Welding.

**079081 STILL WELDING IN THE WASTES?** No, there isn't a misprint in the headline. It really refers to desert waste conditions and not to waste, although there is naturally some of this as well. The one recalls the old 'Karl May', the other a desolate region where one is always thirsty. Those of a romantic nature may perhaps recall an old dream, lounging at an oasis surrounded by a whole bevy of ladies from the harem, letting the sun shine on their bellies. Only very few of the local latitudes can be safely recommended for working in the desert, for example, for welding. Yet that too is more or less on the agenda, for example, when it involves the laying of pipelines in unalloyed steels. (Author abstract) In German and English.

Salko, Djozic. *Schweissen Schneiden* v 39 n 1 Jan 1987 p E13-E15.

**079082 FIELD GIRTH WELDING OF HIGH ALLOY LINE PIPE.** The mechanical and corrosion properties needed for the welding of duplex stainless steel and high alloy internally clad line pipe were investigated. Typical problems experienced in the welding of duplex stainless steel and high alloy internally clad line pipe are low deposition rate in the GTAW process and high weld repair in the SMAW process. Ferrite-austenite balance corrosion resistance and higher productivity were also studied in the field girth welding of duplex stainless steel pipe. The optimum welding material for the welding of high alloy internally clad line pipe was investigated, and the best groove configuration and welding conditions for low dilution were also studied. (Author abstract). 10 Refs. In Japanese.

**PIPELINES, SUBMARINE** See Also PETROLEUM PIPELINES.

**079083 WAVE-INDUCED FORCES ON BURIED PIPELINES.** An analytical model is developed for estimating the pore pressure in the soil and the resulting pressure force on buried pipelines. A solution is developed for a circular, rigid pipeline using conformal mapping techniques. The solution is compared with the results of both small- and large-scale tests; reasonable agreement is obtained for the small-scale tests. Wave-induced seepage forces are evaluated by integrating the pressure distribution over the pipe surface. The magnitude of the force remains constant but the direction rotates around the cylinder once with the passage of each wave. This force may be of sufficient magnitude to be an important consideration in the design of buried marine pipelines. (Edited author abstract) 32 refs.

McDougal, William G. (Oregon State Univ, Corvallis, OR, USA); Davidson, Susan H.; Monkmeyer, Peter L.; Sollitt, Charles K. *J Waterw Port Coastal Ocean Eng* v 114 n 2 Mar 1988 p 220-236.

**079084 WAVE FORCE COEFFICIENTS FOR SUBMARINE PIPELINES.** Wave-induced forces on a submarine pipeline in regular waves placed near a plane boundary were studied in the inertia-drag regime. Rms hydrodynamic coefficients were correlated with Keulegan-Carpenter number or period parameter, gap ratio, and depth parameter. The rms hydrodynamic coefficients were found to depend not only on period parameter and gap ratio but also on depth parameter. The dependence of the hydrodynamic coefficients on depth parameter is such that they decrease with a decrease in depth parameter. The presentation of the results as a single force coefficient, such as rms coefficients, is found to reduce the scatter in the

results considerably and avoids any phase problems. Additional results are discussed. (Edited author abstract) 21 refs.

## Accident Prevention

**079087 OVERHEAD HAZARDS TO SUBSEA INSTALLATIONS.** The growing use of subsea systems has required that traditional onshore and topsides functions be adapted for an underwater environment. While the problems of hydrostatic pressure, buoyancy, hydrodynamic effects and corrosion (for example) leave solutions to be found, the methodology exists to approach these aspects of design which are understandable and well defined. It has not however been historically necessary to develop a process or philosophy onshore or offshore for dealing with a complex regime of 'accidental' loads from overhead. This paper discusses an appraisal methodology, to evaluate overhead regards in subsea installations.

Head, J.W. (KE Int Ltd). *Pipes Pipelines Int* v 32 n 4 Jul-Aug 1987 p 25-26.

## Analysis

**079088 UPHEAVAL CREEP OF BURIED HEATED PIPELINES WITH INITIAL IMPERFECTIONS.** Based on a study of the soil-pipeline interaction, a new design procedure is presented for heated marine pipelines buried in the seabed. It has been observed that geometric imperfections in buried heated pipelines can increase in size with time such that the compressive stresses induced due to thermal expansion and internal pressure can lead to vertical buckling of the pipeline. In the present paper a consistent theory is developed for analysis of imperfect, heated pipelines. It is shown that the observed gradual upheaval can be caused by temperature fluctuations in combination with initial imperfections of the pipeline. For a given pipeline temperature and burial depth the mathematical model can be used to impose restrictions on the allowable imperfections of the unloaded pipe centre line (plastic deformations) combined with restrictions on the allowable imperfections of the trench. (Author abstract). 9 Refs.

## Computer Aided Design

**079089 PROGRESS TOWARDS AN INTELLIGENT COMPUTER AIDED RISK EVALUATION OF PIPELINE DESIGNS.** The design of an offshore pipeline is a complex activity involving teams of engineers and scientists. It is the task of the design team to produce a blue-print for the pipeline which, in addition to satisfying

the primary function of transporting the specified fluid product across the marine environment, must clearly recognize and make appropriate allowances for the many risks to which an offshore pipeline will be exposed, while incurring minimum life cycle costs. The paper discusses results of pipeline reliability studies, and detailed analysis of failures. Refs.

**Construction** See Also PETROLEUM PIPELINES—Offshore; PIPELINES—Construction.

**079090 HOT TAPPING OF SUBSEA PIPELINES.** Over 100 subsea hot taps have been performed worldwide to connect lateral lines to existing submarine pipelines, the majority in the Gulf of Mexico. They include both welded and mechanical type tee fittings. This article reviews the state of the art in subsea hot tapping with particular emphasis on the welding aspects. (Author abstract)

Boran, John (PLT Offshore Ltd). *Weld Rev* v 6 n 4 Nov 1987 p 283-284, 286, 288.

**079091 SUBSEA STRUCTURES AND METHODS INSTALLATION.** Subsea flowlines, vital to the development of future hydrocarbon comprise two main types - steel flowlines and flexible lines. Both have places in fluid transportation, each having advantages and disadvantages in relation to the other. However, once the flowline has been selected the method of installation becomes crucial, particularly with regard to ease of operation and cost. (Author abstract)

Anon. *Mar Eng Rev* Apr 1988 p 36-37.

## Design

**079092 SUBSEA HOT TAPPING: A REVIEW OF APPLICABLE CODES AND STANDARDS.** Hottapping on pipelines has primarily been carried out for the tie-in of lateral lines while maintaining the pipeline under operating conditions. When hot tapping has been combined with stopping techniques it has been used for repair of damaged pipelines without the need to decommission the line. This article reviews the codes and standards applicable to hot tapping on subsea pipelines. Codes are compared for the various aspects of design, construction, installation and testing. Most of the codes have been developed for onshore environments and little reference is made to subsea aspects. The codes mainly address the requirements for welded-type hot-tap fittings, giving little or no consideration to the use of mechanical-type tees. Areas where guidance and future developments are required are outlined. (Author abstract).

**Earthquake Resistance** See Also OFFSHORE STRUCTURES—Structural Design.

**079093 CHOICE OF THE DEPTH OF LAYING SUBMARINE PIPELINES UNDER THE CONDITIONS OF SEISMIC ACTIVITY.** Based on an analysis of the failure rate of pipelines after intensive earthquakes, recommendations are given on the selection of the depth of laying into the soil of underwater pipelines as applied to the pipelines between the North Sakhalin oil and gas wells and the Soviet Far East mainland. It is recommended that 79% of the length of the pipeline should be laid in shallow trenches (up to 1.5 m in depth) and 21% in deep-trenches (from 1.5 to 4.5 m deep). (Translated author abstract) In Russian. 7 refs.

Asta'ev, V.I.; Kandaurov, A.A. *Izv Vyssh Uchebn Zaved Neft Gaz* n 12 Dec 1987 p 75-78.

## Failure

**079094 COLLAPSE OF DEEPWATER PIPELINES.** The paper describes a series of full-scale collapse experiments using X-42 and X-65 grade steel tubes. The

initial geometric imperfections of the tubes were measured using a specially designed scanning facility prior to collapsing them under external pressure. Geometric deviations from a circular shape were recorded at 90 points around the circumference. The wall thickness was also recorded at the same points. At least 31 circumferential scans were made over lengths of 9 diameters. The stress-strain characteristics in the axial and circumferential directions were measured for each tube. The measured parameters were used to calculate numerically the collapse pressures of the tubes. (Edited author abstract) 13 refs.

## Insulation

**079095 DOUBLE PIPE ENSURES RELIABLE INSULATION OF OFFSHORE PIPELINES.** At the beginning of the eighties, the offshore technology relevant to thermally insulated pipelines did not offer a cost-effective and technically challenging solution. Nowadays, the oil industry requires an ever-increasing use of thermally insulated pipelines with improved reliability in the offshore and, more particularly, for the exploitation of arctic fields. The present solution has been developed on the basis of easy handling, conventional laying procedures and long-term integrity criteria adopting a special field joint connector. This type of connector allows the two coaxial pipes to be assembled in a workshop and the individual double pipe sections to be connected in the field by means of a standard butt weld. This paper includes: the presentation of the DPIS (Double Pipe Insulated System) concept, which deals with the structural and thermal insulation aspects relevant to this new system; and a brief description of the first application of the DPIS for a pipeline connecting an unloading terminal for heavy oils to onshore plants. (Author abstract). 10 Refs.

**079096 CONCEPTS FOR MAINLINE PIPELINE TIE-INS.** There are now a large number of pipelines in the North Sea for the transportation of oil and gas. This paper considers the current development of pipelines in the North Sea and then discusses methods by which subsea junctions may be installed in both new and operating pipelines. Operating considerations are identified and conclusions drawn. 1 Ref.

Barber, W.A. (Brown & Root Vickers Ltd). *Underwater Technol* v 14 n 2 Summer 1988 p 3-9.

## Laying

**079097 FLEXIBLE PIPELINES.** A crucial part of an offshore transport system is the pipeline. Underwater pipelines must carry a specified fluid at a given internal pressure, be adequately protected against internal and external corrosion, be able to resist external hydrostatic pressure, and to withstand any loads that might arise in the course of installation. These layered, or flexible, pipelines have been used successfully in offshore oil and gas installations. They are constructed of steel, for mechanical strength, and of thermoplastics, for protection against corrosion and leaks.

Shekher, Vinod. *Mech Eng* v 109 n 2 Feb 1987 p 82-83.

**079098 SUBSEA PIPE BURIAL.** The laybarge Delta I broke its own record for laying and burying pipelines in a 24-hr period on April 16, 1987. The contractor laid and buried, to a depth of 3 ft in 60 ft of water, a total of 9,158.3 ft of 6-in. pipe in the period. The line is part of a gas gathering system being built by Corpus Christi Oil & Gas in West Cameron Block 238, offshore Louisiana. The Mudbug was used in the project.

Anon. *Pipeline Gas J* v 214 n 10 Oct 1987 p 33-35.

**079099 PIPELAYING FROM A BARGE.** New problems in the laying of steel pipelines on to the sea-bed have appeared with the advent of relatively deep water, offshore oil and gas developments. The laying of these pipelines from a barge is controlled by the geometry of the stinger and the applied tension. Correct settings of these two parameters are essential to ensure that the pipe does not suffer any damage during its installation. A three-dimensional, large rotation model, for which the state of deformation of the pipe is described by three angles, is presented. A model in which the deformation is described by two-angles is also considered, so enabling a comparison to be made with previously published models. It is shown that the profile of the pipe is restricted by the neglect of the third angle. A critical assessment of two-angle modeling of these systems is made. (Author abstract) 23 refs.

Brown, M.J. (Univ of Leeds, Leeds, Engl); Elliott, L. *Math Eng Industry* v 1 n 1 1987 p 33-46.

**079100 HYDROSTATIC PRESSURE IS SECRET OF 'HYDROPULL' PIPELAYING METHOD.** The hypopull technique for laying submarine pipe was invented about 12 years ago. The employment of hydrostatic pressure is the basic operating principle behind the hypopull technique. Pipe sections are still lowered into place in the traditional manner. The difference, however, manifests itself most readily in the two watertight bulkheads that are fundamental to the hypopull concept. One bulkhead is left stationary, normally capping the upstream end of the first pipe section to be installed. The other bulkhead, the actual hypopulling unit, is normally chained to the bell end of the pipe section being lowered into place. An integral part of this bulkhead is a motorized impeller driven by pressurized hydraulic fluid. The fluid is fed through hose that connects the bulkhead to a hydraulic pump positioned on the work barge. When the pump is activated, water is driven from the inside of the pipe section. The beauty of this technique lies in the suction effect that is created when the joint starts to come together. By driving water from the pipe, a pressure differential is created whereby tons of hydrostatic force are effectively harnessed. This force acts to push the pipe sections together to form a tight joint.

Ganas, Michael J. (Boswell Underwater Engineering). *Sea Technol* v 29 n 4 Apr 1988 p 21-24.

**079101 PARAMETRIC INFORMATION FOR LAY-BARGE INSTALLATION OF SUBMARINE PIPELINE.** A method is described for obtaining the onboard information for the safe laying of pipeline by lay-barge technique. With the help of the method, the effect of the quasi-static barge motion on the installation stresses in the pipeline is also investigated. The procedure for selecting the values of the control parameters for the safe laying of the pipeline including the effects of current and barge motions is then discussed. The method consists of an analytical procedure for the solution of the suspended pipeline under its own weight and current by using a finite difference formulation. The results of the analysis are composed into a set of graphical plots from which the necessary information is extracted to prepare the onboard data for the safe laying of pipeline and also to investigate the effect of barge motions. The method is illustrated with the help of a numerical example on a 75 cm O-D pipeline to be laid in 170 meter depth of water. (Author abstract). 16 Refs.

## Removal

**079102 UNDERWATER OPERATIONS FOR DECOMMISSIONING OF SUBSEA PIPELINES AND RELATED FACILITIES.** This paper considers the underwater operations required for decommissioning pipelines installed in the North Sea Continental Shelf areas. The type of work is described under the areas of

survey/inspection/measurement, valve/mechanical manipulation, cutting/welding and lateral/vertical movement. The subject of excavation is also discussed in the paper. Work requirements, methods and techniques available are defined within three groups: divers (saturation), remotely operated vehicles (ROVs) and manned submersibles. Consideration is given to the difficulties that may occur on the seabed for decommissioning and removal of pipelines. To illustrate this, a number of typical problems are described. They are complete pipeline burial, fixed seabed pipeline structures, connecting pipelines, seized pipeline end connectors, damaged/buckled pipelines, severe internal corrosion and crossing pipelines. It is then proposed that specialized equipment may need to be designed and developed for particular recovery operations. Such equipment could be a pipe-lift seabed crawler, a de-burial plough, a de-burial jetting sled and special reeling equipment. (Edited author abstract)

## Structural Analysis

**079103 ANALYSIS OF BUCKLE INITIATION IN DAMAGED SUBSEA PIPELINES.** A rigid, perfectly plastic mechanism analysis, embodying interactive uniaxial membrane and bending plasticity, is used to predict the form of localized impact damage for tubulars. An extension of the model allows the pressure response of a pipe containing damage, and in particular the pressure at which buckling is initiated in a damaged pipeline. Test results are shown to confirm the validity of the mechanistic approach employed in predicting the damage process, while initiation tests based on a different initial imperfection configuration are shown to reproduce the trend of predicted initiation pressures. An attempt to improve the buckle performance through the use of spirally rib-reinforced pipelines is also described. (Edited author abstract) 13 refs.

Tam, C.K.W. (Univ Coll London, London, Engl); Croll, J.G.A. *J Offshore Mech Arct Eng* v 109 n 4 Nov 1987 p 366-374.

**079104 NONLINEAR ANALYSIS OF FLEXIBLE RISERS USING HYBRID FINITE ELEMENTS.** A method is developed for the static and dynamic analysis of flexible risers and pipelines in the offshore environment under conditions of arbitrarily large motions due to wave loading and vessel movements. A mixed finite element formulation is adopted where the axial force is independently interpolated and only combined with the corresponding axial displacements via a Lagrangian constraint. An advantage of the resulting hybrid beam element is that it may be applied to offshore components varying from mooring lines or cables to pipelines with finite bending stiffnesses. Results are presented for the motions and forces on a flexible riser connecting a tanker to a subsea tower and also on a combined flexible riser and subsea support buoy structure which is part of a floating offshore production system. (Author abstract). 13 Refs.

## Testing

**079105 ON THE COLLAPSE STRENGTH OF SUBMARINE PIPELINES.** A simplified method of analyzing the collapse strength of submarine pipelines subjected to combined bending, external pressure and axial force is presented. In this analysis, the collapse load is determined by investigating both the limit load types of failure and bifurcation of the compressed region. A computer program 'PCOLAS' is devised based on the theory. Because of the simplicity of the method, the collapse behavior can easily be investigated. The theoretical results agree well with available test results for combined bending and external pressure. (Edited author abstract) In Japanese. 3

## Wave Effects

**079106 ROOT MEAN SQUARE FORCE COEFFICIENTS FOR SUBMARINE PIPELINES.** An experimental investigation has been carried out on forces induced by regular and random waves on submarine pipelines placed near a plane boundary. The inline and transverse forces are analyzed in terms of combined root mean square (rms) hydrodynamic coefficient. The total rms coefficient is correlated with Keulegan-Carpenter number or period parameter and relative clearance of the pipeline from the plane boundary. The pipeline was subjected to Pierson-Moskowitz spectrum (P-M spectrum) in the random wave force tests. The time histories of water particle kinematics are generated using the linear numerical transforms. This paper also reports the effect of depth parameter on the total rms coefficient. The results of the random wave force tests are finally compared with those of regular waves. (Author abstract) 17 refs.

**079108 STEAM OR ELECTRIC TRACE HEATING: WHICH SHOULD YOU CHOOSE?** Steam tracing has been the standard method for maintaining process temperatures and preventing freeze-ups. While steam systems are noted for being safe and reliable, they are both energy and labour intensive. With escalating costs, many plant engineers have begun to seek a more cost-effective alternative, such as electric trace heating systems. The most significant development of the 1970s was that of self-regulating trace heating. The concept was introduced by California-based Raychem in its AutoTrace system, and other companies have followed with similar products. The principle behind self-regulating tape is that its power output automatically decreases as its temperature rises. The Raychem tape comprises a carbon polymer matrix extruded between two copper busbars. The factors to be evaluated in selecting the trace heating system are considered and a software program designed to give a direct comparison of costs is described.

**079109 PRESSURE PULSATION IN A CENTRIFUGAL PUMP-PIPING SYSTEM (1ST REPORT, EXPERIMENTAL EXAMINATION OF CHARACTERISTICS FOR PRESSURE PULSATION).** In piping systems, including centrifugal pumps, a pressure pulsation is generated. In this report, a centrifugal pump is assumed to have two characteristics: one is the generation of pulsation and the other is the propagation of waves. The combination of these two characteristics is linear, and the latter is described by a transfer matrix. The values of these characteristics are obtained by experiments and the above assumption is confirmed. The mechanism for pressure

pulsation generation and the roll of the pump in pressure pulsation are grasped more exactly. The pulsation source of a centrifugal pump is the pulsating pump head. These experiments make it clear that the strength of the pulsation source is independent of piping systems, and its amplitude and phase are both almost constant at constant revolutions of the impeller. (Author abstract). 14 Refs. In Japanese.

**079110 PRESSURE PULSATION IN A CENTRIFUGAL PUMP-PIPING SYSTEM (2ND REPORT, PRESSURE DISTRIBUTION IN A PIPE AND EFFECTS OF PUMP CONFIGURATION ON PRESSURE PULSATION).** A centrifugal pump is assumed to have two characteristics for pressure pulsation: one is the generation of pulsation and the other is the propagation of waves. In this report, pressure distributions in a pump-piping system with the same pump as the first report are obtained by experiments, and are compared with calculated values based on the result of the first report. The pressure pulsation may be explained clearly based on the propagation and generation phenomena of pressure waves in a simple pipe system of reasonable length, instead of a pump. Effects of pump configuration on the pressure pulsation become clear by experiments using two dimensional centrifugal pumps which have a different divergent angle of the volute, clearance gap between an impeller and a tongue, and blade number. (Author abstract). 9 Refs. In Japanese.

## Accident Prevention

**079111 SAFETY IN GAS SYSTEMS.** The article discusses the potential hazards in gas systems using the destruction of a building in New York City by natural gas explosion as an illustration. This example serves as an excellent guide to three principles for safe gas system installations: design the system to satisfy the system demands while minimizing the opportunity for failure; integrate the gas system design and location with those of the other building systems; ensure that construction and installation of all parts of the gas system conform precisely to the design specifications. The author suggests some general rules for designing/installing gas piping systems.

## Cold Weather Problems

**079112 COLD WEATHER DESIGN OF PLUMBING SYSTEMS.** A recent, in-depth study of various utilities in freezing climates provides information enabling an engineer to predict if freezing will occur, and discusses various methods that can prevent freezing. These studies show that the freezing process of water in pipes is more complicated than originally thought, and is different for both static and flowing water. A formula is discussed which is developed to determine ice formation on an open vessel's surface and considers the insulating effect that the forming layer of ice has on the transfer of heat from the surface of the water to the air. The derivation of the basic formula for frost depth is discussed.

## Components

**079113 STRESS INTENSITY FACTORS FOR TWO DIFFERENTLY SHAPED CIRCUMFERENTIAL SURFACE CRACKS AT THE OUTER WALL OF A PIPE.** The exclusion of failure of components of the

piping systems of a reactor by crack growth is often proved by experimental studies of pipes having artificially produced surface flaws. In many cases - especially for circumferentially oriented flaws - the shape of these flaws doesn't coincide with the semi-elliptical surface crack model commonly used in fracture mechanics. Therefore the stress intensity factors of such flaws are not exactly known, which may cause some problems in the interpretation of the experiments. In this paper the results of finite element calculations of two differently shaped circumferential surface cracks at the outer wall of a pipe are presented. 4 refs.

## Computer Simulation

**079115 SIMULATION OF FLUID PIPES IN HYDROSTATIC CIRCUITS USING MODAL AND SEGMENTED METHODS.** Distributed parameter systems can be simulated by cutting the system, like a fluid pipe, into slices or segments. Or one can use a method based on solving a partial differential equation with suitable boundary conditions, and assign a bondgraph R, I, C combination to each mode or eigenfunction. This contribution compares both approaches for a fluid power hose and determines the superior accuracy of the model approach. Variation of the terminating resistor influences the resonant frequencies, and depends not on the resistance alone, but on a suitable non-dimensional combination with the global capacitance and inductance of the hose as suggested by dimensional analysis. Simulations were carried out by the CAMP and ACSL programs on one side, and by TUTSIM and FANSY programs on the other side; the results confirm each other. (Author abstract) 10 refs.

## Corrosion Protection

**079116 INSITUFORM'S VERTICAL TAKE OFF AT HEATHROW.** The 'Insituform' system which has been for many years well established in the field of pipe lining in sewers and pipes in the water, chemical and petroleum industries has recently moved into a new area lining vertical drain pipes in the oldest British Airways hangar at London's Heathrow Airport. Travers Morgan & Partners, the East Grinstead-based consulting engineer, was called in by British Airways to find a solution to the problems caused by the corrosion of mild steel drain pipes encased in the reinforced concrete columns inside the hangar. A review of the solution is presented in this article.

## Cracking

**079117 ATTAINMENT OF HIGH VALUES OF THE APPLIED TEARING MODULUS FOR CIRCUMFERENTIAL CRACKS IN STAINLESS STEEL PIPING SYSTEMS.** When assessing the stability of a crack in a Type 304 stainless steel Boiling Water Reactor piping system, for the displacement-controlled loading conditions that are appropriate to an accident situation, the accepted procedure is to determine the applied tearing modulus  $T_{APP}$  and compare this with the material tearing modulus  $T_{MAT}$ ; high  $T_{APP}$  values therefore favor crack instability. This paper presents a general analysis which gives  $T_{APP}$  for a circumferential through-wall crack in a straight pipe segment of length  $L$ , where one end is subject to fixed deformations, while the boundary conditions at the other end are flexible, thereby reflecting the interaction with the remainder of the piping system. (Edited author abstract) 5 refs.

**079118 FUNDAMENTAL CONCEPTS OF TWO-PHASE FLOW IN UPWARDS SLOPING PIPELINES.** Experimental data obtained by the author shows that the results can be predicted which theoretically lead to a semi-empirical approach for pressure drop and transition to slug flow. The geometry of a suggested piping system is defined through five lengths, A-B, B-C, C-D, D-E and E-F. In addition the slope angles for the five segments are needed to complete the description of the system. It is the purpose of this paper to discuss the rather large effects that the geometry of such a system may have on the flow in it. In addition, some observations from a series of experiments with inclined pipes will be discussed. (Edited author abstract) 3 refs.

**079119 PIPING METHOD FOR ACCOMMODATING PIPE OFFSETS.** A procedure is described for calculating a number of couplings, grooved pipe spool lengths, and displacements to accommodate pipe run offsets due to misalignments or building settlement. The offset transition can be achieved only with flexible couplings since they allow for angular deletion at each joint. Offsets are determined by the amount of lateral misalignment on the particular pipe run and the length along the pipe run that is required for the parallel shift of the run. (Edited author abstract)

**079120 HOW TO PREDICT PRESSURE DROP BEFORE DESIGNING THE PIPING.** In the design of process and power plants, it often is necessary to estimate the pressure drop of a piping system before all the required information is available. A correlation developed by W.B. Hooper accurately predicts the number and type of valves and fittings per unit length for piping of various sizes. These predictions, combined with the known line lengths and published equivalent-length factors, provide an accurate estimate of the true equivalent length and, therefore, the pressure drop. This article converts the data presented by Hooper into equations for estimating pressure drop. This method has been found to be very useful for preliminary estimates of pipe use size and pressure drop, for checking final design calculations to see whether they are reasonable, and even for ordering pumps and compressors in cases where the frictional pressure drop is relatively small compared with the total pressure drop. The method is applied by means of an example. 3 refs.

**079122 PIPING DESIGN CRITERIA AND RESEARCH: CURRENT NRC ACTIVITIES IN DYNAMIC DESIGN.** The current design process for nuclear power plant piping relies heavily on detailed dynamic response analyses. The criteria and design practices used in this process were themselves justified largely by analytical studies using judgment about high level response and failure mechanisms. Now, 'physical' data from recent dynamic failure tests and earthquake experience surveys indicate that the overall design margins for piping dynamic loads are much greater than previously believed. Conservatism is introduced in three general areas of the piping design process: (1) piping input loads (2) piping response calculation, and (3) ASME Code piping design criteria. 42 refs.

**079123 POSITIVE USE OF DAMPING DEVICES FOR PIPING SYSTEMS - SOME EXPERIENCES AND NEW PROPOSALS.** An increase of the damping ratio is known to be very effective for the seismic design of a piping system. It is reported that the energy dissipation in piping supports contributes to increase the damping ratio of the piping system. In this paper, with regard to increasing the damping and reducing the seismic response of the piping system, three application methods of damping devices used in other engineering fields are reviewed: (1) direct damper, (2) dynamic vibration absorber, and (3) connecting damper. Based on the results of this review, the following three types of damping devices for piping systems are introduced: (1) visco-elastic damper (direct damper), (2) elasto-plastic damper (direct damper), and (3) compact dynamic absorber (dynamic vibration absorber). (Edited author abstract) 14 refs.

**079124 ACCUMULATED DAMAGE EVALUATION FOR A PIPING SYSTEM BY THE RESPONSE FACTOR ON NON-STATIONARY RANDOM PROCESS (1ST REPORT, A SINGLE-DEGREE-OF-FREEDOM SYSTEM).** This paper shows that the average and variance of the accumulated damage caused by earthquakes in a piping system are related to the seismic response factor. The earthquakes in this paper are of a non-stationary random process. The average is proportional to  $\lambda^2$  and the variance is to  $\lambda^4$ . The analytical values of the average and variance for a single-degree-of-freedom system are compared with those obtained from computer simulations. Both averages of accumulated damage are approximately equal. The variance obtained from analysis does not coincide with that from simulations. The reason is considered to be the fluctuation in power spectra of input accelerations and a small number of sample data. But increasing the number, the average and variance become approximately equal for both analysis and simulation. (Author abstract) In Japanese. 12 refs.

**079125 COUPLED SEISMIC RESPONSE OF PIPING AND LIQUID COLUMN (3RD REPORT, SEISMIC RESPONSE OF BENDING PIPELINE).** To estimate the coupled seismic response of a 3D piping system and an internal pressurized fluid, and to make clear the difference between the coupled model and the conventional dead mass model of fluid, a calculation method was applied. This method is based on the model analysis for piping structural response and the characteristics method for fluid response, and the coupling was considered by fluid force to pipe and variable boundary conditions to fluid. The response in each condition was compared with that of the dead mass model, and the following results were obtained: (1) The dead mass model, in some cases, has given unconservative estimation in acceleration response, but no significant difference in displacement response comparing with the coupled model. (2) The induced pressure is about the same level in the soft and hard support system and is possible to reach the negative pressure in a resonance response of a low pressure and low friction system. (3) The system including a constant pressurized tank has generally shown the higher response in acceleration and pressure than the system without tank. (Edited author abstract) In Japanese. 4 refs.

Ogawa, Nobuyuki. *Nippon Kikai Gakkai Ronbunshu C Hen* v 54 n 497 Jan 1988 p 143-150.

**079126 ACCUMULATED DAMAGE EVALUATION FOR A PIPING SYSTEM BY THE RESPONSE FACTOR ON NON-STATIONARY RANDOM PROCESS (2ND REPORT, A TWO-DEGREE-OF-FREEDOM SYSTEM).** This paper shows that the average and variance of the accumulated damage caused by earthquakes on the piping system attached to a building are related to the seismic response factor  $\lambda$ . The earthquakes referred to in this paper are of a non-stationary random process kind. The average is proportional to  $\lambda^2$  and the variance to  $\lambda^4$ . The analytical values of the average and variance for a single-degree-of-freedom system are compared with those obtained from computer simulations. Here the model of the building is a single-degree-of-freedom system. Both averages of accumulated damage are approximately equal. The variance obtained from the analysis does not coincide with that from simulations. The reason is considered to be the forced vibration by sinusoidal waves, and the sinusoidal waves included random waves. Taking account of amplitude magnification factor, the values of the variance approach those obtained from simulations. (Author abstract) In Japanese. 13 refs.

**079127 PIPING SEISMIC ADEQUACY CRITERIA RECOMMENDATIONS BASED ON PERFORMANCE DURING EARTHQUAKES.** Design and analysis of piping in a typical nuclear power plant has been estimated to cost as much as \$80 million, at least 60% of which is associated with the implementation of current seismic design criteria. These current design criteria require seismic qualification of nuclear plant piping based on rigorous and expensive mathematical analysis and testing. Past earthquake experience has shown that piping within power facilities which have undergone little or no seismic qualification have performed very well with only a limited number of resulting cases in which the pressure boundary has been breached. The purpose of this paper is to document the performance of piping in past earthquakes and to explore the possibilities of using the results of this earthquake experience data to guide the development of a more reasonable criteria for assessing the seismic adequacy of power piping. (Edited author abstract) 6 refs.

**079128 SIMPLIFIED METHOD FOR INELASTIC PIPING SYSTEM SEISMIC RESPONSE PREDICTION.** This paper presents a seismic response prediction method based on a simplified plastic system analysis. The analysis uses a dynamically equivalent static-g loading that has been adjusted for inelastic energy dissipation. The simplified plastic system analysis utilizes an incremental series of equivalent static-g loadings and replaces yielded components with hinge elements when a predefined hinge moment is reached. This hinge moment value is selected to result in inelastic energy absorption of the same magnitude as observed in piping component dynamic tests and analyses. Two definitions of dynamically equivalent static-g loadings are employed: one conservatively based on the peak of the design acceleration response spectrum, the other based on modal analysis results of the simplified plastic system model. A comparison of predicted results versus experimental results is provided for a high-level seismic test of a representative LWR piping system. (Edited author abstract) 41 refs.

**079129 EXPERIMENTAL AND ANALYTICAL STUDIES OF PIPE WHIP TESTS UNDER PWR LOCA CONDITIONS.** A series of pipe rupture tests has been performed at the Japan Atomic Energy Research Institute (JAERI) to demonstrate the safety of primary coolant circuits in the event of pipe rupture in nuclear power plants. Pipe whip tests and jet discharge tests have been conducted under boiling water reactor (BWR) and pressurized water reactor (PWR) loss-of-coolant accident (LOCA) conditions. The present paper describes the experimental and analytical results of the pipe whip tests performed under PWR LOCA conditions using 4, 6 and 8-inch test pipes. The tests were carried out at an initial pressure and temperature of 15.7 MPa and 325°C, respectively. Moreover, a dynamic analysis of pipe whip tests was carried out using the general purpose finite element program ADINA. (Author abstract) 10 refs.

**079134 COOLANT FLOW RATE LIMITERS FOR USE IN PIPELINE FAILURE.** The Dzerzhinskii All-Union Heat-Engineering Institute has developed restrictive inserts that can be placed within a pipeline at points of junction with components of larger cross section to reduce the critical flow rates considerably in the emergency escape of coolant from a nuclear power station. An Inventors' Certificate has been issued for the method of constraining the specific flow rate by intensifying the boiling. The design of the inserts is based on the following assumptions: an insert should have a resistance less than the limiting permissible value in the nominal working state and should provide a considerable reduction in the leak flow rate in the emergency state when the pipe breaks. 3 refs.

**079135 EXTRUDED CONNECTIONS SOLVE PIPING PROBLEMS.** Stress cracking on FCCU pipe air grids has long been a problem for refiners. This cracking is one of the primary problems that continually needs to be remedied during planned or unplanned shutdowns. A successful solution to this maintenance problem is the use of extruded connections instead of traditional reinforcing saddles or stub-in welding designs. The extruded outlet header design is not a new concept, having been widely used in pipeline applications for decades. Its acceptance in refinery applications, has surfaced within the past few years. Examples show how extruded header connections give better service life than fabricated branch connections in several refinery applications.

**079138 EXPERIMENTAL EVALUATION OF THE LONG-TERM STRENGTH OF REINFORCED PLASTIC (GRP) PIPES.** The long-term mechanical strength of glass-fiber-reinforced polyester resin pipes is studied in internal pressure tests. The initial pressure resistance of the pipe structure and the strain in the pipe wall were measured. The longest running times of the pressure tests reached nearly 40,000 h. The results of all pressure tests are extrapolated according to the procedure in the ASTM standard to give an estimate of the strength of the pipe after an expected period under certain stressed conditions. A certain correlation is found between evaluations based on short- and long-term measurements. Behavioral differences during the pressure tests were also found to be related to differences in the pipe structure. (Edited author abstract) 10 refs.

**Safety Valves**

**079139 SIZING EXCESS FLOW VALVES.** The use of Liquefied Petroleum Gases (LPG) as a fuel is widespread in both industry and in private homes. LPG consists of mixtures of propane, butane, and other alkanes which are normally stored and used at temperatures above the normal boiling point. An excess flow valve is a device that is designed to stop the flow of a material when the flow rate exceeds a preset limit. It is the author's belief that a safety device, such as an excess flow valve, should have a reasonable chance of working in the event of an accident. If the safety device can not be designed with a reasonable chance of working, it should not be installed. The critical parameter needed to select an excess flow valve is the expected flow rate through the valve during an incident. This paper will present a calculation method (based on recent developments in two-phase flow modeling) to estimate the actual limiting flow that can be expected in LPG piping systems. 14 Refs.

## Standards

**079140 PRESSURE VESSEL AND PIPING CODES.** Much of the piping in a nuclear plant is designed to the ASME Boiler and Pressure Vessel Code, Section III, Class 2 or 3 requirements. The Code rules are given in NC/ND-3600 of Section III. These rules were developed from the B31.1 rules, and incorporated into Section III 1971 for nuclear components. However, the Class 2/3 piping Code requirements have changing significantly since that time. There is not a criteria document available from ASME that describes the Class 2/3 piping rules. The purpose of this paper is to provide background information and a discussion of the Code stress limits so that the piping analyst can properly interpret the meaning of the Code requirements. (Author abstract.) 11 refs.

Slagis, G.C. (G.C. Slagis Associates, Walnut Creek, CA, USA). *J Pressure Vessel Technol Trans ASME* v 110 n 3 Aug 1988 p 329-334.

## Structural Analysis

**079141 NUMERICAL ALGORITHM FOR ANALYZING PIPING RESPONSE TO THERMAL TRANSIENTS AND SEISMIC EXCITATIONS.** This paper describes a three-dimensional finite-element method for the structural response analyses of reactor piping systems subjected to thermal transients and seismic excitations. In the thermal-transient analysis, the algorithm appropriately accounts for stresses arising from the temperature dependence of the elastic material properties, the thermal expansion of the materials, and the change in the temperature-dependent yield surface. It includes a thermoviscoplastic constitutive equation that incorporates capabilities of treating thermal softening, failure, strain rate, creep, and stress ratcheting. In the piping seismic analysis, a time-history method is utilized to account for possible nonlinear phenomena as well as to reduce the solution conservatism obtained from response-spectrum analyses. Variation in dominant stress frequencies and translational frequencies are easily handled. (Edited Author abstract) 17 refs.

Wang, Chung-Yi (Argonne Natl Lab, Argonne, IL, USA). *Nucl Eng Des* v 106 n 1 Feb 1 1988 p 147-160.

**079142 DYNAMIC RESPONSE ANALYSIS OF THE PIPING SYSTEM CONSIDERING NONLINEAR CHARACTERISTICS OF SUPPORT (2ND REPORT, INFLUENCE OF FRICTION ON SUPPORT).** This investigation deals with the seismic response analysis of a pipe-support system with friction characteristics. The friction characteristics are assumed to be as the Coulomb friction model. This paper highlights, particularly, the effect of friction forces upon the maximum response of the piping system subjected to random excitations including seismic motions as follows: (1) The maximum response of the piping is generally suppressed by the growth of friction force. (2) The response reduction factor based on the maximum response of the linear piping is proposed. This factor can be obtained only through the ratio of the natural period of piping to that of the supporting structure. (3) The other response reduction factor is proposed. (Edited author abstract) In Japanese. 11 refs.

**079143 MODAL DECOUPLING METHODS FOR FLUID-STRUCTURE INTERACTION IN PIPING SYSTEMS.** A simple model for fluid-structure interaction in piping systems is considered, using beam elements for the structure and assuming the propagation of planar pressure waves in the fluid. The forces, exerted, on the structure at the 'singular' points of the piping system due to the change of the fluid momentum, are treated in a natural and straightforward way. The model is shown to behave quite well in the low frequency range, provided that certain corrections are made to the structure inertia, to the structure flexibility at the 'singular' points (elbows,

tees, etc) and to the fluid sound speed. Recent advances concerning the general 'acoustoelastic' fluid structure model - symmetrisation procedures, modal decoupling methods - are applied to the model. The modal methods start with the solution of the 'in vacuum' and of the 'acoustic' eigenproblems and lead to the solution, not only of the 'full' eigenproblem, but also of several 'limit case' eigenproblems, such as the 'incompressible' fluid. (Edited author abstract.) 18 refs.

Antoniadis, I. (Natl Technical Univ of Athens, Greece); Kanarachos, A. *Comput Struct* v 29 n 4 1988 p 577-585.

**079144 EFFECTS OF PLASTICITY ON DYNAMIC RESPONSE OF PIPING STRUCTURES.** The analysis of elastoplastic structures under a combination of static and dynamic loads is examined. It is shown that under the hypothesis of a ductile behavior, progressive distortion is the leading failure mechanism. Procedures are described to compute: (a) the equivalent damping due to hysteretic losses; (b) frequency shifting due to structural softening in the plastic fields; (c) ductility effects on dynamic loads; and (d) ratcheting due to a combination of static and dynamic loads. (Author abstract.) 32 refs.

Lazzeri, L. (Ansaldo SpA, Genoa, Italy). *J Pressure Vessel Technol Trans ASME* v 110 n 3 Aug 1988 p 263-269.

## Structural Design

**079145 DESIGN OF PIPING IN PLASTIC CONDITIONS UNDER DYNAMIC LOADS.** The problem of the design of piping in plastic conditions under dynamic loads is discussed making reference to an analog, by which frequency shifting, damping and ratcheting are found. A comparison between the criteria based on damping increase and the ductility ones is made showing that the usual values are compatible with ductilities between 5 and 10, depending on the static value. It is shown that very large increases over yielding can be sustained by the structure (even in the elastically perfectly plastic scheme) with moderate ductility values; in this way dynamic loads should be regarded basically as secondary ones. (Edited author abstract) 19 refs.

Lazzeri, L. (Ansaldo SpA, Genoa, Italy). *Int J Pressure Vessels Piping* v 30 n 5 1987 p 351-365.

**079146 WATER HAMMER PRODUCTION AND DESIGN MEASURES IN PIPING SYSTEMS.** Water hammer in piping systems produces large dynamic forces, which can damage the pipes and supports. Therefore, it is important to minimize the water hammer and its effects on the piping system. In this work, reduction of the water hammer by active measures is described - that means the reduction of water hammer effects by influencing the fluid dynamic conditions of the system. Where these measures give no satisfactory results, design measures to control the dynamic forces are described. The article does not claim to be complete, but it does give the engineer some aspects of the design of the piping system and the supports. (Author abstract.)

## Supports

**079147 STANDARDIZATION OF PIPING SUPPORTS IN NUCLEAR POWER PLANTS USING PRETESTED COMPONENTS.** The article reports on the 'standard piping-support catalog', which was used in connection with the Convoy-nuclear-power-plants in the Federal Republic of Germany, under special consideration of: (i) cost reduction for planning and installation, (ii) suitability tests (type testing for standardized supports), and (iii) application of CAD. The advantages using the piping support catalog are summarized. (Author abstract.)

**079148 DECREASING SNUBBER INSERVICE INSPECTION COSTS THROUGH SNUBBER REDUCTION AND IMPROVED TEST LIMITS.** Snubber inservice inspection (ISI) requirements, along with a history of snubber malfunctions, has made inspection and maintenance of snubbers a significant part of a nuclear power plant's ISI budget. These expenses can be minimized through snubber reduction and the use of improved test limits for snubber functional testing. This paper presents a snubber overview and reviews snubber ISI requirements. Examples are given of the high cost that maintaining a snubber in an operating nuclear plant represents. (Edited author abstract) 14 refs.

Olson, D.E. (Sargent & Lundy, Chicago, IL, USA); Tang, Y.K. *Nucl Eng Des* v 107 n 1-2 Apr 1988, Curr Issues Relat to Nucl Power Plant Struct, Equip and Piping-Sel Pap, Raleigh, NC, USA, Dec 10-12 1986 p 183-199.

**079149 WIRE ROPE SEISMIC SUPPORT.** Current piping system snubber reduction programs have shown that the number of snubbers can be reduced by the use of optimization computer codes and solid engineering design experience. Many engineering firms claim snubber reduction as high as 50%. Unfortunately, these claims are often based on ideal situations without any design constraints. A new energy absorbing seismic support is presented which can eliminate all snubbers in a nuclear power plant. In addition, the support has application for supporting sensitive plant equipment which must withstand earthquake loadings at reduced G-levels. The device is simple and inexpensive. The proposed device has been utilized in military, satellite, warship, space shuttle, aircraft and off-road vehicle applications for the past 20 years. The use of the device in such applications has resulted in conformance to government and military specifications along with quality control requirements similar to those of the nuclear industry. (Author abstract)

**079150 SEISMIC STOPS VS. SNUBBERS, A RELIABLE ALTERNATIVE.** The Seismic Stops methodology has been developed to provide a reliable alternative for providing seismic support to nuclear power plant piping. The concept is based on using rigid passive supports with large clearances. These gaps permit unrestrained thermal expansion while limiting excessive seismic displacements. This type of restraint has performed successfully in fossil fueled power plants. A simplified production analysis tool has been developed which evaluates the nonlinear piping response including the effect of the gapped supports. The methodology utilizes the response spectrum approach and has been incorporated into a piping analysis computer program RLCA-GAP. Full scale shake table tests of piping specimens were performed to provide test correlation with the developed methodology. Analyses using RLCA-GAP were in good agreement with test results. (Edited author abstract) 3 refs.

**079151 DIFFERENCES IN DYNAMIC RESPONSE OF TYPICAL CLASS II PIPING DUE TO RESTRAINT METHOD AND INPUT AMPLITUDE.** A 50-ft (15.2 m) section of pressurized 8-in. and 6-in. (200 mm and 150 mm) piping with multiple bends and a simulated motor-operated valve was tested using shake table techniques to note differences in piping response and in stress levels due to the incorporation of four different pipe restraint devices. These devices included a rigid element, a mechanical shock arrestor, a hydraulic snub-

ber, and a new, unique triaxial visco-elastic piping damper. The latter device was configured in two ways. (Author abstract) 2 refs.

## Valves

**079152 APPLYING AIR RELEASE VALVES IN PIPING SYSTEMS.** Potentially damaging pressure surges and vacuum conditions which may occur in piping systems can be avoided with the judicious use of air release valves described here. Air release valves are hydro-mechanical devices which automatically vent small pockets of air as these accumulate at high points in a piping system while the system is operating and under pressure. An air/vacuum valve is float operated and has a large discharge orifice equal to the size of the valve's inlet. This type automatically allows large volumes of air to be exhausted or admitted into a system, as required. Combination air valves have the operating features of both air/vacuum valves and air release valves. Combination air valves can be installed at all high points of a piping system where it has been determined both air/vacuum valves and air release valves are needed to properly vent and protect the system. (Edited author abstract).

**Vibrations** See Also COMPRESSORS—Piping Systems; NUCLEAR POWER PLANTS—Earthquake Resistance.

**079153 OVERCOMING STEAM HAMMER IN HIGH PRESSURE PIPEWORK.** The event known as 'steam hammer' is set up by the turbine stop valves slamming shut after a turbine trip. Compression waves generated at the stop valves travel up the Main Steam and Hot Reheat lines towards the boiler. As the turbine cylinder is starved of steam the pressure in it drops, and a rarefaction wave is generated. This travels up the Cold Reheat towards the boiler. In the fluid flow analysis of steam hammer, the pressure transients and resulting unbalanced forces acting on the pipework are calculated. A number of commercially available computer codes, such as Relap or Wavenet can be used for this. The numerical solution scheme of Relap is based on a finite-difference integration method. Wavenet has a smaller range of applicability, and uses the method of characteristics to solve the wave equations explicitly. The models built for the static design of the system can be used providing the software has facilities for time-history analysis. Software available for this purpose include: Superpipe and Babcock's Pipestress 2000. The authors argue that steam hammer analysis should be carried out at the design stage, using the recommendations made for fully modeling the boundary conditions in the fluid transient analysis, as they will produce more realistic results.

**079154 VIBRATIONS DES TUYAUTERIES SOUS ECOULEMENT: PREMIERES ANALYSES.** [Flow Induced Vibrations in Piping Systems: First Analysis]. Industrial piping systems conveying fluids are very often submitted to undesired vibrations. Those phenomena are generally related to flow singularities (pumps, valves) and can be of different nature: a) The vibrations are very strong, and lead to a fast failure of the structures. Those instabilities are linked to a strong interaction between the source and the response; b) The vibrations are at a lower level, and generate damages by fatigue. In that case, the

fluid excitation can be characterized by random sources which are not connected to the system response. The aim of this report is to summarize the main theoretical models for prediction of random excitation due to the fluid unsteadiness, and to give some industrial examples. **079155 BESTIMMUNG DER RADIALDRUCK-VERTEILUNG AN KOLBENRINGEN.** [Distribution of Radial Pressure on Piston Rings]. Pressure distribution is a decisive factor for the sealing function, the operating characteristics, and the wear of piston rings. On the basis of the theory of bending test beams and by measuring the form of the untensioned geometry, the procedure described in this article deduces the radial pressure distribution in the installed piston ring. On a shape analyzing device, the contact surface of the piston ring is scanned over its circumference in an untensioned state. The relationship between radial pressure distribution and the untensioned piston ring shape is represented in a simulation model. (Edited author abstract) 6 refs. In German.

Neumann, Peter; Rau, Norbert; Heubner, Gerd. *MTZ Motortech* v 48 n 11 Nov 1987 p 467-469.

## Deformation

**079156 UNERWUNSCHT E PLASTISCHE VERFORMUNG DES KOLBENRINGES.** [Undesirable Plastic Deformation of the Piston Ring]. This article deals with the traditional piston ring made of either pearlitic grey iron or - increasingly - nodular iron. The problem is plastic deformation of the ring in the area opposite the gap due to excessive stress. This high stress is the result of gaps and/or radial widths that are too large. The plastic deformation changes the pressure pattern which the manufacturer has taken great pains to give the ring. This, though, usually remains undetected, since the deformation occurs during the process of installation. Unless one is willing to undertake a radical departure from the conventional concept of the piston ring, the answer can only be: reduced free gap widths and radial widths to improve conformability, use of back-up springs to increase wall pressure and stiffer engine blocks to reduce thermal distortion of the cylinder. The resulting additional cost would have to be accepted in the interest of quality. (Edited author abstract) In German.

## High Temperature Properties

**079158 HOT PISTON RING TESTS.** As part of the DOE/NASA Automotive Stirling Engine Project, tests were made at NASA Lewis Research Center to determine whether appendix gap losses could be reduced and Stirling engine performance increased by installing an additional

piston ring near the top of each piston dome. Unlike the conventional rings at the bottom of the piston, these rings operated in a high temperature environment (700°C). Because of this, we called them 'hot-rings'. It was necessary that they be made of a high-temperature alloy (Stellite 6B) and that a high-temperature solid lubricant coating (NASA Lewis-developed PS-200) be applied to the cylinder walls. Results indicated a slight increase in power and efficiency with the hot-rings over the baseline configuration. This increase was over and above the friction loss introduced by the hot-rings. Seal leakage measurements showed a significant reduction in leakage with the hot-rings in place. (Edited author abstract) 2 refs.

## Iron

**079159 ENHANCING THE QUALITY OF PISTON RING IRON.** A study has been made of the influence of various complex modifiers on the structure and properties of piston rings 210, 230 and 260 mm in diameter, made from a nodular iron (ChShG). The iron was melted in a type ICHT-1 induction furnace from a metallic charge comprising 30% steel-making pig iron (grade PVK-1), 10% steel scrap and 60% internal scrap, and superheated to 1480-1520°C. The green clay-bonded sand molds were poured at 1350-1380°C. The pots (piston ring blanks) of wall thickness 20-35 mm were knocked out after 30 min and cooled in air. Modification with the master alloy ZhKMK-4R, with up to 6% Ca and 4% REM, followed by late modification with FS75, produces irons with superior machinability and a stable surface finish after machining with ceramic-tipped tools. During running in, the piston rings provide a uniform pressure distribution over the cylinder walls; they are extremely reliable and durable.

## Lubrication

**079160 CALCULATING METHOD OF OIL FILM THICKNESS IN PISTON RING PACK WITH CONSIDERATION OF STARVED LUBRICATION.** S. Furuhashi's piston ring lubrication theory is analysed in this paper. The main deficiency in the prediction of piston ring pack working under fully flooded condition has been indicated. In light of the mentioned deficiency, the authors develop an approach to oil film thickness prediction considering starved lubrication. Finally, the calculated film thickness values obtained by both methods are compared with the measured results. (Edited author abstract) 3 refs.

Wang, Ducai (Xi'an Inst of Technology, China); Chen, Zhaoxiang; Zhu, Wenjun. *Neiranji Gongcheng* v 9 n 1 1988 p 60-67.

**079161 FULL AND STARVED LUBRICATION MODEL OF PISTON RING PACK.** D. Dowson et al. published an article dealing with the lubrication of a piston ring pack in which the starved lubrication of a piston ring was considered. It marked a giant leap in this field. But there are still some defects in it. In order to eliminate them, a new model of full and starved lubrication of a piston ring pack is put forward and the numerical procedure is presented. There are calculation examples at the end of the paper. The values of the film thickness of the piston ring in an engine calculated under the new model are closer to the measured ones and agree well with what occurred in practice. (Edited author abstract). 5 Refs. In Chinese.

## Design

**079163 ANALYSIS TECHNIQUE USED IN THE DESIGN OF THE SPHEROIDAL CAST IRON PISTON OF CONCAVING COMBUSTION CHAMBER.** This paper uses an analysis technique to analyze the spheroidal iron piston of concaving combustion chamber in detail. The analysis consists of a calculation of the piston thermal stress and mechanical stress by using the finite element method and an evaluation of the life of the piston. An analysis of the failure probability due to the nature of the material used and the degree of dispersion of the load of the piston is also considered. The analysis shows that the radial crack of the spheroidal iron piston throat of the concaving combustion chamber displays a -433MPa thermal circular stress and creep because of fatigue interaction. (Edited author abstract) 4 refs. In Chinese.

## Fluid Dynamics

**079165 DEFLECTION OF A PISTON.** This paper concerns itself with the determination of the detection of an annular plate exerting a pressure on a fluid-filled cylinder, a problem which can occur in machine design when describing the action of a piston. For the purpose of this analysis, the cylinder is considered to be 'rigid' while the fluid can be compressible or incompressible. The load

P is applied by means of a shaft rigidly attached to the inner edge of the plate. The outer edge is considered to be either guided in the cylinder or free to rotate. It is furthermore assumed that the effect of buoyancy is negligible. It can be eliminated by letting a thin layer of fluid cover the top of the plate. 4 refs.

## High Pressure Effects

**079168 SEALING UNIT FOR PISTONS OF HIGH-PRESSURE DEVICES.** A sealing unit for pistons of high-pressure (up to 2 GPa) devices is described that consists of a thin-walled elastic sleeve with conical inner and outer surfaces, which is implemented as one piece with a guide bushing, which, in turn, is sealed relative to the vessel wall by a ring. (Author abstract) 4 refs.

Cherepov, S.V. (Acad of Sciences of the Ukrainian SSR, Kiev, USSR); Chernenko, V.A. *Instrum Exp Tech* v 30 n 1 pt 2 Jan-Feb 1987 p 233-235.

**079169 USE OF CONTROLLED-CLEARANCE HIGH-PRESSURE BALANCES WITH HIGHLY VISCOUS PRESSURE TRANSMITTING MEDIA.** It is shown that in the case of a nonlinear dependence of the zero-clearance pressure  $p_z$  on the measured pressure  $p$ , controlled-clearance high-pressure piston-cylinder systems can be operated over large portions of their measurement range at constant jacket pressure  $p_j$ . This suggests characterizing the effective area by the equation  $A_e = A_0 (1 + \lambda p - d \cdot p_j)$  with the deformation coefficient  $\lambda$  defined as for 'simple' piston-cylinder systems. It is confirmed experimentally that  $\lambda$  and  $d$  do not depend on the measured pressure or on the jacket pressure. The standard pressure balance used to measure the parameters  $A_0$ ,  $\lambda$  and  $d$  of two controlled-clearance piston-cylinder systems has been checked against the mercury melting line. The measuring method is described and results are reported. If use is made of the mercury fixed point of the pressure scale, controlled-clearance high-pressure balances operated with viscous media can be characterized independent of a primary standard by measurement uncertainties of a few parts in 10,000. (Edited author abstract) 4 refs.

## Reliability

**079174 PARTIALLY STABILIZED ZIRCONIA PISTON BOWL RELIABILITY.** The Weibull based 'Simplified Structural Ceramic Design Technique' was used to calculate the reliability of a partially stabilized zirconia (PSZ) piston bowl design. The details of the method and a set of sample calculations are presented. Test results of the piston bowl showed cracks in regions which had a high calculated probability of failure. In addition cracks developed in a region of high compressive/shear stress. Since Weibull reliability analysis only uses tensile stresses this area did not have a high calculated probability of failure. Several hypotheses are presented for the mode of failure in this region. The simplified technique was used to predict what the necessary material properties would have to be for successful PSZ insert of the design shown. (Author abstract) 10 refs.

Hartsock, D.L. (Ford Motor Co, Dearborn, MI, USA). *J Eng Gas Turbines Power Trans ASME* v 109 n 4 Oct 1987 p 367-373.

## Seals

**079175 DEVELOPMENT OF A NEW COMPACT PISTON SEAL.** From a seal supplier's viewpoint it is vital that existing product ranges are manufactured efficiently and that new ranges are designed, developed and manufactured using the latest CAD-CAM techniques. New ranges must also be capable of operating with wider parameters and show real savings to the user. Hallite Seals International has introduced a new range of compact piston seals for use in light, medium and heavy duty hydraulic cylinders.

Anon. *Power Int* v 33 n 389 1987 p 162-163.

## Testing

**079176 CHOICE OF METHOD FOR CHECKING PISTON TEST SYSTEMS AND VOLUME DETERMINATION RELIABILITY ESTIMATION.** A basic condition for providing reliability in determining PTS (Piston Test Systems) volumes is that there is no liquid leak during the check. To test for the absence of leaks, the standardization documentation envisages determining the volumes at two flow rates:  $V_1$  the larger and  $V_2$  the smaller. In practice,  $\Delta_1$  may be positive or negative; if  $\Delta_1$  is more than 0.2Δ and is positive, this usually indicates a leak. It is then necessary to check for leaks in the piston device or in the four-way stopcock and to adjust the piston to increase the thrust and repeat the measurements. If  $\Delta_1$  is negative and larger in value than 0.2Δ, this indicates errors in the measurements. One can judge the measurement performance and the quality of the PTS from the standard deviation in the results, as the quality of the measurements and the PTS increases as the standard deviation decreases. 5 refs.

## PLANETARIUMS

## Bangalore, India

**079177 MODERN PLANETARIUM COMPLEX IN BANGALORE.** A modern planetarium is recently constructed in the garden city of Bangalore. Situated near the Raj Bhavan, the planetarium complex, costing Rs. 2.28 crores, is one of the best in the country. The complex has a total area of about 2,650 m<sup>2</sup> and comprises a 300-seat sky theater, exhibition area, lecture halls, revolving dome with claude telescope, children's art gallery, and services. The elegant-looking buildings are attractively clad with sandstone from Rajasthan. The whole complex is enveloped by delightful greenery and extensive landscaping. (Author abstract).

Nath, Prem. *Indian Concr J* v 62 n 5 May 1988 p 235-237.

## Equipment See OPTICAL PROJECTORS—Automation.

## Instruments See Also OPTICAL PROJECTORS—Performance.

**079178 COSMORAMA - JENA'S LATEST PLANETARIUM DESIGN.** In July 1984 the Space Sciences Centre was opened in Edmonton (Canada). Visitors experienced the first planetarium shows with the new COSMORAMA projection machine supplied by JENOPTIK JENA GmbH. Designed for large domes 17.5 to 25 m in diameter, the COSMORAMA can impressively demonstrate the starry sky to several hundred spectators at a time. A brief survey of the development that led to this planetarium designed in Jena is given. The instrument is the world's first large planetarium to be controlled exclusively through microcomputers. 3 refs.

## PLANETS See Also SPACECRAFT—Mathematical Models.

## Exploration

**079179 TOWARDS BECOMING A MULTI-PLANET SPECIES.** The future exploration of the solar system will be a mix of humans and machines working together. In some cases the human-machine link may be over thousands to tens of million kilometers. In other cases it may be just a few meters, as humans themselves visit and work on other planets. In addition to the scientific investigation and the possible development of utilitarian applications on other planets, one of the principal aims of solar system exploration is to understand and develop the role of humans off of the planet Earth. One can conceive of very limited roles with occasional forays of exploration or of much more involved roles, leading to possible colonization on other planets. More limited models may be valid with machines doing most of the investigation - such as in our underwater activities in the ocean. It is to be emphasized here, and specifically cited later, that saying this is not to set up Mars missions as having priority over other space (or terrestrial) activities. 13 refs.

Friedman, Louis (Planetary Soc, Pasadena, CA, USA). *Space Technol (Oxford)* v 7 n 3 1987 p 217-225.

**079180 REACHING FOR THE PLANET MARS: HUMANKIND'S EVOLVING PERSPECTIVES.** The historical background provides a broad range of perspectives of Mars commencing with the realization that a point of light called Mars was a wanderer or planet. The viewpoint of many people early in this century, based upon a paucity of data, was that the Martian environment was earthlike. Mars was thought to be inhabited. The realization now is that the Martian environment is radically different than the terrestrial. Fundamental questions in comparative planetology arise regarding the environments of Earth, the Moon, Venus and Mars, which have important implications for the terrestrial environment and man's approach to that environment. Mars is the keystone of comparative planetology. To learn the nature of Martian atmospheric and solid body dynamics is also to learn of competing processes at work on all of the terrestrial planets. (Author abstract) 26 refs.

## Remote Sensing See EXTRATERRESTRIAL ATMOSPHERES—Remote Sensing.

## PLASMA ARC CUTTING See Also CONCRETE CONSTRUCTION—Radiation Effects; METAL CUTTING—Laser Beam; METALS AND ALLOYS—Fatigue; WELDING—Sensors.

**079181 AIR PLASMA CUTTING DEVELOPMENT AND PRESENT TRENDS IN EQUIPMENT AND APPLICATIONS.** Principles of the process, equipment

and techniques used, and applications and current developments are described. Topics include a history of air plasma cutting, formation and effects of the plasma, electrodes (water cooled copper electrodes with hafnium or zirconium inserts), the drag cutting technique, safety, fume, applications removal, new equipment, and the scope of the process case histories are given.

Harris, Ian (Welding Inst, Abington, Engl). *Met Constr* v 19 n 10 Oct 1987 p 586-590.

**079182 NEW CATHODE MATERIALS FOR AIR-PLASMA CUTTING.** The air-plasma cutting technique is very simple, and comparatively low current up to 50 A is mainly applied. The cathode is a small-tip electrode made of zirconium or hafnium, tightly mounted in copper sheath. At these tip electrode are exposed to oxidizing atmosphere at high temperatures, the durability of the electrode material is a serious problem. In this paper, it is shown that a new material which is obtained by sintering of rhenium (Re) and yttrium-oxide (Y<sub>2</sub>O<sub>3</sub>) mixture, a superior durability can be achieved.

Matsuda, Fukuhisa; Ushio, Masao; Umez, Sadao. *Trans JWRI* v 16 n 1 Jun 1987 p 215-216.

## Automation

**079183 PLASMA ARC CUTTING SYSTEM PROVES A CUT ABOVE THE ORDINARY.** From its plant in Martinsville, Va., Koger/Air designs, builds and installs dust collection and air handling systems. Metal cutting is a major part of the fabricating process, and until 1986, all cutting was done manually or supplied by outside vendors. The recent installation of an MG Mini-bridge 3500 with a Hypertherm HT400 automated plasma cutting system has had a major and very positive effect on the business. Koger's cutting applications cover a wide selection of metals and thicknesses - galvanized, stainless steel, carbon steel and aluminum, from 24 gauge to 1 in. thick. The paper describes the benefits obtained by Koger with the installation of its new automated plasma arc cutting system. A description is given of the software features of the new system which has included some accounting functions. Productivity improvements and the adaptation of the employees to the new cutting operations are also reviewed.

Anon (American Welding Soc). *Weld J (Miami Fla)* v 67 n 2 Feb 1988 p 45-46.

## Computer Applications See MACHINE SHOPS—Computer Applications.

## Control Systems

**079184 MICROPROCESSOR-BASED SHAPE AND VELOCITY CONTROL SYSTEM FOR PLASMA ARC CUTTING.** Plasma arc cutting is a fusion cutting process in which a gas-constricted arc is employed to produce a high-temperature, high-velocity plasma jet on the workpiece. This process provides some advantages, such as increased cutting velocity, excellent working accuracy and the ability to cut special materials (widely used stainless steels and Al-alloys, for example), when compared to conventional oxyfuel gas cutting. From the viewpoint of price and reliability of the power source, plasma arc cutting also has some distinct advantages over laser beam cutting. The paper discusses a software program which allows any shape composed of line and circle to be cut with great accuracy using the plasma arc cutting process.

Na, S.-J. (Korea Advanced Inst of Science & Technology, Seoul, South Korea); Park, S.-W.; Cho, S.-H.; Lho, T.-J. *Weld J (Miami Fla)* v 67 n 2 Feb 1988 p 27-33.

## Efficiency See SHEET AND STRIP METAL—Cutting.

## Equipment

**079185 PLASMA ARC CUTTING POWER SUPPLIES EXPLAINED.** Since 1980, there have been two major trends in the plasma cutting industry. The first

has been the rise of small systems (under 100 A) to market dominance, and the second is the use of more electronics in the power supply design. The market shift to small power supplies has resulted primarily from the development of new markets for small systems in such areas as HVAC, sheetmetal fabrication and auto body fabrication, as well as a relatively flat demand for large systems from heavy industry. This article will focus on the three most common types of small power supplies and will compare their relative merits. The three types of plasma cutting power supplies in common use today are the drooper, the inverter, and the chopper. The drooper is a 'conventional' power supply, while the other two are referred to as switchmode supplies.

Frappier, M.B. (Thermal Dynamics Corp, West Lebanon, NH, USA). *Weld J (Miami Fla)* v 67 n 2 Feb 1988 p 48-50.

## Measurements

**079186 RADIAL CURRENT-DENSITY DISTRIBUTION IN THE MAIN SPOTS IN A PLASMA CUTTING ARC.** Air-plasma metal cutting is increasingly used, where the plasmatron may have a thermochemical cathode or a cylindrical copper electrode. A major distinctive feature is that the arc burns between the inner electrode and the metal to be cut and passes through a narrow nozzle along with the air. Intense heating and rapid melting occur in the arc spot on the metal, while the plasma flux through the nozzle blows the molten metal away, and the spot moves along the generator in the cutting cavity. The efficiency and economy in plasma cutting are dependent to a considerable extent on the heat transfer between the arc spot and the metal, and the rate of this is dependent on the spot parameters, particularly the radial current-density distribution. Measurements have been made on the current density in a cutting arc as affected by polarity and by the design and working parameters. (Edited author abstract) 7 refs.

Kiselev, Yu.Ya. (Kishinev Polytechnical Inst, USSR); Pogora, V.K. *J Eng Phys* v 53 n 2 Aug 1987 p 950-953.

## Personnel

**079187 WHAT DISTRIBUTORS SHOULD KNOW ABOUT PLASMA ARC CUTTING.** When it comes to thermal cutting, the oxyfuel process faces competition from plasma arc cutting. One reason is that oxyfuel cutting is slower in many cutting operations than the plasma arc process, which first came into use some 30 years ago. Another reason is improvements in the portable handheld air plasma torches which reduce the cost of plasma arc cutting considerably.

Jefferson, Ted B. (Welding Distributor, Cleveland, OH, USA). *Weld Distrib* 32 n 3 May-Jun 1988 p 76-78.

## Quality Control

**079188 QUALITY OF PLASMA-ARC CUTTING AND AEROSOL-GENERATION.** Underwater plasma cutting is a method of thermal cutting, whereby a high performance (thickness of metal to be cut 10 mm), the small tool required, and no restoring forces are all advantages. A high temperature plasma arc (about 25,000 K) cuts electrically conducting materials by melting and partially evaporating them. The melted or evaporated particles produced either remain in the water in solution or in assistance of coarse-grained or hollow spheres or become partially aerosol depending on the parameters of cutting. The possible methods of recognition and analysis of the cutting products are discussed. Interpretation of the results shows that the quality of plasma cutting depends on the degree of aerosol-generation. 2 refs.

**079189 INITIAL RESULTS FROM THE COAXIAL SLOW SOURCE FRC DEVICE.** The Coaxial Slow Source (CSS) is a device in which 'annular' FRCs, i.e., small aspect ratio, highly elongated plasmas with poloidal fields only, are formed in the annular space between concentric coils carrying toroidal currents. The device is constructed so that the plasma can be translated into a simple cylindrical chamber and re-formed as a true FRC. The goal of the investigation is to form FRCs on slow (diffusive) time-scales and at low voltage. Initial operation shows that the desired configurations are formed over a wide range of coil voltages and fill pressures. The radial plasma position can be controlled. Configuration life-times are 30-60  $\mu$ s, with flux lifetimes of 15-20  $\mu$ s. Flux is built up over 25  $\mu$ s, at loop voltages of 1-2 kV, in comparison with 2.5  $\mu$ s and 100 kV for comparably sized field reversed theta pinches conventionally employed for FRC generation. (Author abstract) 16 refs.

**079190 GROUND-BASED PLASMA CONTACTOR CHARACTERIZATION.** This paper presents recent NASA Lewis Research Center (LeRC) plasma contactor experimental results, as well as a description of the plasma contactor test facility. The operation of a 24 cm diameter plasma source with hollow cathode was investigated in the 'ignited-mode' regime of electron current collection from 0.1 to 7.0 A. These results are compared to those obtained with a 12 cm plasma source. Full two-dimensional plasma potential profiles were constructed from emissive probe traces of the contactor plume. The experimentally measured dimensions of the plume sheaths were then compared to those theoretically predicted using a model of a spherical double sheath. (Edited author abstract) 11 refs.

**079192 PG-45 PLASMA GENERATOR.** Processes have been developed in the USSR and abroad that use low-temperature plasma; to introduce these into industry the All-Union Scientific Research Institute for Electrothermal Equipment has developed the PG-45 plasmas generator. Series production began in 1986. The device is provided with the following: a basic power supply consisting of a series KTE thyristor converter and a power transformer; a supply unit for the keep-alive arc; an arc plasma gun; a high-frequency oscillator; a water-cooling system that includes gages for flow rate and temperature of the cooling water; a gas-supply system that includes systems for regulating and measuring gas flow rate; control panels and console. A figure shows a plasma gun

of linear arrangement with a fixed arc length.

Bortnichuk, N.I. *Sov Electr Eng* v 58 n 11 1987 p 114-115.

**079193 FINITE PRESSURE EQUILIBRIUM EFFECTS ON HELICAL RIPPLE TRANSPORT IN TORSATONS.** A three-dimensional equilibrium code (NEAR) is used to study plasma equilibrium in torsatron configurations having various winding laws. The harmonic spectra describing the variation of  $|B|$  along magnetic field lines are calculated at finite plasma pressure and then used to calculate the geometric factors that determine the magnitudes of the neoclassical transport coefficients in the helical ripple regime, where the particle and heat fluxes are inversely proportional to the collision frequency. The results show that an appropriate choice of winding law can reduce helical ripple transport by a factor of about 2 in the vacuum field and at high plasma pressure. (Author abstract) 14 refs.

## Accelerators

**079194 EFFICIENCY ASPECTS OF SHORT, LOW VELOCITY RAILGUNS.** The factors controlling the performance of short, low velocity railguns are studied and mathematical expressions defining the bounds of realizable efficiencies are obtained. The restrictions governing the validity of the expressions are discussed. The expressions are based on the proposition that during acceleration of the projectile in the railgun, the current falls almost linearly with time. Under the conditions discussed in this report it is shown that the maximum achievable efficiency is about 1.6%. 13 refs.

Sach, C.I. *Rep Mater Res Lab Aust MRL-R-1029 Jun 1987 30p.*

**079195 ANALYSIS OF A SERIES OF ELECTRO-MAGNETIC LAUNCHER FIRINGS.** In this report theoretical aspects of electromagnetic launchers are presented in conjunction with an analysis of diagnostic measurements taken during the RAPID Plasma Intensity Profiles (RPIP) series of firings. These theoretical aspects deal with the current-time behavior, the plasma temperature and the evaluation of railgun parameters such as the efficiency and effective inductance per unit length. The principal aims of the RPIP series were: (1) to see if different types and masses of plasma-generating foils affected railgun performance and the diagnostic measurements taken during each firing and (2) to compare some of the theoretical predictions of the Plasma Armature Rail Accelerator (PARA) simulation code with experimental results. Projectile displacement-time results for the series were obtained by digitizing photographs from a streak camera and in order to verify the PARA predictions for plasma-length behavior, light intensity profiles were produced from microdensitometer readings of the streak films. The experimental results were affected by plasma disruption, arcing ahead of the projectile and plasma leakage. These effects are also discussed in this report. (Author abstract) 38 refs.

Kowalenko, V. *Rep Mater Res Lab Aust MRL-R-1053 Jun 1987 85p.*

**079196 EVALUATION OF ACCELERATION AND HEATING OF PARTICLES BY PULSED PLASMA FLOW.** Using a simplified approach, based on the shortness of the discharge time compared with the time of plasma flow out of a pulsed accelerator, it is possible to evaluate the parameter of the plasma flowing out of the accelerator barrel. A relation proposed taking into account of the effect of the shape of the solid particles on their aerodynamic resistance, as well as a method of calculating the nonsphericity coefficient, are proposed. The calculation of the velocity of the particles in a pulsed

flow corresponds well with the experiments. It is shown that acceleration of the particles of the hard cobalt-tungsten carbide alloys VK-25 is accompanied by their melting and partial evaporation, which makes it possible to explain the lack of correspondence between the sizes of the carbide grains in a coating with the sizes of the powder being sprayed. (Translated author abstract) 10 refs. In Russian.

**079201 CHARGED-PARTICLE BEAM GENERATION IN A VACUUM MICROWAVE DISCHARGE INITIATED BY EXPLOSIVE EMISSION.** It is shown that the plasma formed by explosive emission (EE) in a high-power microwave field is a source of charged particles (electrons and ions). Stable ion-beam generation is observed only when the cathode has an extended emitting surface. It is found that the expansion velocity of the plasma for small gaps in the diode is lower than with EE in pulsed fields. (Edited author abstract). 5 refs.

Andriyanov, Yu. V.; Bazdyrev, V.N.; Borisov, D.A.; Zhukov, V.M. *Sov J Commun Technol Electron* v 32 n 9 Sep 1987 p 139-145.

**079202 CHARGE FLOW AND PLASMA BEHAVIOR IN INTENSE ION BEAM DIODES.** Spatial nonuniformities of the diode plasmas, plasma expansion, ion transverse velocities in the diode gap, electron flow to the anode, and the charge distribution in the gap have been investigated for magnetically insulated diodes. Rapid closure of the diode gap, resulting from fast expansion of the electric field, was observed, excluding anode plasma early in the pulse. This contributes significantly to the measured ion-current-density enhancement. The electron cloud in the gap spread toward the anode beyond the region of the theoretical electron sheath, which is consistent with observed ion current densities being larger than the values calculated using the actual diode gap. The ion angular spread increased locally due to nonuniform expansion of the cathode plasma for one class of phenomena of the anode plasma for two other classes. The ion divergence angle in the gap was independent of the ion mass and significantly smaller than angles previously observed outside the diode. 35 refs.

**079206 OPTIMIZATION OF THE PROCESS AND APPARATUS FOR PLASMA SPRAYING.** The variational problem of optimization of thermophysical and gas dynamic processes in a high temperature flux during plasma spraying is formulated with the purpose of minimizing the losses of the powder sprayed. The solution is based on a steady-state quasi one-dimensional model of high temperature flux of a non-ideal gas with particles. Calculation results show a good match with experimental data. (Translated author abstract) 12 refs. In Russian.

Gonopol'skii, A.M. *Izv Sib Otd Akad Nauk SSSR Ser Tekh Nauk* n 4 Feb 1988 p 81-88.

**079207 GEOMAGNETIC FIELD - AN EXPLANATION FOR THE MICROTURBULENCE IN COAXIAL GUN PLASMAS.** The complexity introduced by the geomagnetic field in several regions of a coaxial gun plasma device is described. It is shown that the annihilation of the swept-up geomagnetic flux, trapped within the highly compressed turbulent plasma, provides an explanation for varied performance and experimental results. The results indicate that the device should be aligned along the direction of the local geomagnetic field or enclosed in a mu-metal shield. 2 refs.

Mather, J.W. (Univ of New Mexico, Albuquerque, NM, USA); Ahluwalia, H.S. *IEEE Trans Plasma Sci* v 16 n 1 Feb 1988 p 56-57.

#### Heat Transfer

**079208 FLUID FLOW AND HEAT TRANSFER IN PLASMA REACTORS - I. CALCULATION OF VELOCITIES, TEMPERATURE PROFILES AND MIXING.** A mathematical representation has been developed to describe the velocity field and the associated temperature and concentration fields in a plasma jet system, which involves the injection of additional gas streams. In the statement of the problem, allowance was made for the swirl of the plasma jet, and one important objective of the work was to explore the effect of this swirl on the principal process variables. It was found that swirl plays an important role in providing mixing between the plasma jet and a reactant or diluent gas stream. (Edited author abstract) 25 refs.

## Ion Implantation

**079209 PERFORMANCE OF A PLANAR MAGNETRON SPUTTERING APPARATUS WITH COMPLEX TARGET.** A planar magnetron sputtering apparatus with complex targets has been made for depositing high quality metal films onto various substrates. The apparatus can be used in several configurations such as that for multilayer, interdigitated wedge deposition and co-sputtering. The vacuum chamber contains four pairs of two-element targets and a rotatable substrate holder, which permits eight elements to be deposited onto one substrate without removal of the substrate from the vacuum chamber. A liquid nitrogen trap is used for cooling the substrate. (Edited author abstract) 12 Refs.

**079210 PARTICLE DYNAMICS AND PARTICLE HEAT AND MASS TRANSFER IN THERMAL PLASMAS. PART III. THERMAL PLASMA JET REACTORS AND MULTIPARTICLE INJECTION.** Thermal plasma processing involves complex interactions of particulates with plasma. A mathematical model is proposed for the simulation of thermal plasma jet reactors, including the mixing phenomena between the jet and the surrounding gases by generalizing the governing equations for simple mixing flows. Also included is the density fluctuation effect by extending the K- $\epsilon$  model to a four-equation turbulence model combined with a probability density function. For multiparticle injection, the simulation repeats calculations for single-particle injection, but with different initial conditions correcting the solutions by considering the coupling effects between particles and the plasma. (Edited author abstract) 35 refs.

**079211 DYNAMIC CHARACTERISTICS OF A DENSE PLASMA JET IN THE ATMOSPHERE.** The electrical characteristics of a plasma-dynamic accelerator with a gas fill are studied. The dynamics of a dense plasma jet in air at atmospheric pressure was studied with the help of ultrafast photography and the Schlieren technique. It is shown that for impulsive injection of a dense plasma jet into the atmosphere a spherical shock wave and a cloud of intensely radiating plasma, from which under certain conditions a stable long-lived toroidal or spherical plasma configuration forms, are produced. (Author abstract) 8 refs.

**079212 INFLUENCE OF THE BLOWOFF OF BOUNDARY GAS FROM THE DISCHARGE CHAMBER OF A PLASMATRON ON THE PARAMETERS OF THE JET.** The results of an experimental investigation of the parameters of an argon jet heated in a plasmatron with an anode permitting the removal of part of the cool gas from the discharge chamber are presented. An analysis of the results of the measurements show that removal of the cool part of the working gas from the discharge chamber of a plasmatron has slight influence on the maximum temperature near the nozzle. This indicates that under the given conditions, the electric arc in the anode behaves like an unventilated body to a certain extent, while the hot gas mixes insignificantly with the cool boundary stream. An increase in the fraction of removed gas makes the radial temperature distribution level off much more. (Edited author abstract) 20 refs.

**079213 INFLUENCE OF A WEAK MAGNETIC**

**FIELD ON THE INTENSITY OF THE PLASMA JET OF AN ARC PROTON SOURCE.** An arc source of a plasma jet, used as an element of a system of plasma diagnostics or as the injection system for a proton accelerator, experiences the influence of the stray magnetic fields of these systems. The influence of a longitudinal magnetic field with an induction  $10 < B < 70$  G on the arc source leads to an increase in the density of the plasma jet generated by it and of the current extracted from the fixed plasma boundary in proportion to B. A similar result was obtained in the range of strong magnetic fields  $300 < B < 800$  G. The influence of longitudinal magnetic fields with  $B < 13$  G on these parameters is analyzed in the present paper in connection with problems of stabilization and control of the current of a source. 7 refs.

**079214 PROBE DIAGNOSTICS OF THE LATE STAGES OF OUTFLOW OF A DENSE PLASMA JET INTO THE ATMOSPHERE.** Data are given on the evolution in time and space of the electron concentration in a plasma jet, ejected into the air from the nozzle of a powerful pulse plasmatron. These data are obtained using the probe method and the uhf method. It is shown that during the late stage of outflow (up to times of 1.5-2 msec) typical values of the electron density range from  $10^{14}$  to  $10^{13}$  cm $^{-3}$  and change little during the indicated time interval. (Author abstract) 12 refs.

Andres, A. (Moscow State Univ, USSR); Ershov, A.P.; Isaev, K.Sh.; Timofeev, I.B. *High Temp* v 25 n 4 Jul-Aug 1987 p 566-570.

**079215 PROBE MEASUREMENTS IN THERMAL PLASMA JETS.** Measurements of composition, temperature, and velocity in atmospheric argon plasma jets are reported, using enthalpy probes. The plasma jets are generated by a commercial type plasma gun and the measurements are expected to be of particular interest for individual applications such as plasma spraying. Emphasis has been on the central and downstream regions of the plasma flame. The environment of air into the jet was found to be very high, even close to the axis of the jet. Gas samples analyzed with a gas chromatograph showed demixing of the air, i.e., nitrogen is more abundant in the jet than at room temperature. (Edited author abstract) 40 refs.

Brossa, M. (Univ of Minnesota, Minneapolis, MN, USA); Pfender, E. *Plasma Chem Plasma Process* v 8 n 1 Mar 1988 p 75-90.

**079216 TEMPERATURE STUDIES OF A SUBSONIC JET IN MOLECULAR GASES AT LOW PRESSURES.** The results of measurements of the temperature in an air and nitrogen plasma jet at low pressures on the VGU-2 setup are presented. The flame of the air and nitrogen plasma jet has a characteristic structure: a high-temperature core and a peripheral part - a mixing layer with a lower temperature. The core of the nitrogen plasma jet is wider than that of the air plasma jet for the same values of the pressures and powers. (Edited author abstract) 7 refs.

Georg, E.B. (Acad of Sciences of the USSR, Moscow, USSR); Yakushin, M.I. *J Eng Phys* v 53 n 3 Sep 1987 p 1045-1050.

**079217 TEMPERATURE MEASUREMENTS OF ATMOSPHERIC AIR PLASMA FREEJETS BY MEANS OF THE MOIRE-SCHLIEREN AND SPECTROSCOPIC METHODS.** The atmospheric Ar plasma freejets, generated by an electric arc discharge, are visualized and measured by the Moire-Schlieren method to obtain the details of their higher temperature fields. Electron temperatures and electron number densities are also deduced from a combined method of the absolute measurement of Ar spectral lines and the collisional-radiative process theory. From the experiments performed under the conditions of arc currents of 100-200 A and nozzle diameters of 3-4 mm, the following are found: (i) The gas temperatures are 1000-5000 K and the electron

temperatures are about 8500 K. (ii) The distributions of gas temperature for the conditions show a similar form. (iii) The freejets are thermally in nonequilibrium, though the plasmas are fairly dense. (Author abstract) In Japanese. 19 refs.

**079218 SIX-ELECTRODE, DIRECT-CURRENT, VARIABLE-LENGTH PLASMA SOURCE FOR ATOMIC EMISSION SPECTROSCOPY.** A variable-length plasma source has been developed for analytical atomic emission spectroscopy. The length of the plasma, adjustable during plasma operation, provides a means of adjusting the sample residence time in the plasma. The plasma operates from three compact, simple, and inexpensive direct-current power supplies. Three concentric quartz tubes supply argon and sample aerosol to the plasma. The modular design allows the quartz tubing to be easily replaced and a variety of electrode distances to be established. The argon consumption, typically 7.4 L/min, is comparable to, or less than, that for commercial DCP and ICP systems. Many of the vertical spatial characteristics of the plasma described are similar to those documented for the ICP. Changes in the nebulizer gas flow rate produced spatial shifts in the maximum of the vertical, spatial analyte emission profiles of Mg. Increases in the signal-to-background ratios at common analytical wavelengths were observed with increasing plasma length. (Edited author abstract) 62 refs.

**079219 SPATIAL STUDY OF THE INFLUENCE OF PLASMA LENGTH ON INTERFERENCE EFFECTS IN A SIX-ELECTRODE, DIRECT-CURRENT, VARIABLE-LENGTH PLASMA.** Vertical spatial profiles of a six-electrode, direct-current plasma emission source were used to study the influence of plasma length on the interference of Na on Ca and Zn and P on Ca. For the shortest plasma (11.5 mm) depression of the Ca atom line is observed in the region up to 10 mm above the tip of the sample bullet when Na is present. A cross-over to enhancement occurs for higher regions. This is directly opposite to the observations in the ICP for the Na interference on Ca. Increasing the plasma length causes downward shifts in the crossover point which are not a simple effect of the lowering of the sample bullet. When P is present, the Ca atom emission is initially depressed in the region directly above the sample bullet. At higher observation heights, little effect is observed. Similar behavior is observed for the Ca ion line in the presence of P, suggesting the possibility of a classical vaporization-type interference mechanism. The interference effects studied can be eliminated by careful selection of plasma length and observation height. (Edited author abstract) 21 refs.

## Research

**079221 CURRENT-VOLTAGE CHARACTERISTICS AND POTENTIAL OSCILLATIONS OF A DOUBLE LAYER IN A TRIPLE-PLASMA DEVICE.** The properties of a strong double layer in a current circuit with a capacitance and an inductance are investigated in a triple-plasma device. The double layer gives rise to region of negative differential resistance in the current-voltage characteristic of the device, and this gives nonlinear oscillations in the current and the potential drop over the double layer ( $\Phi_{DL}$ ). A variable potential minimum exists in the plasma on the low-potential side of the double layer, and the depth of the minimum increases with  $\Phi_{DL}$  increases. An increasing fraction of the electrons incident at the double layer are then reflected, and this is found to be the main process giving rise to the negative differential resistance. A qualitative model for the variation of the minimum potential with  $\Phi_{DL}$  is proposed. 23 refs.

## Vacuum Applications

**079224 VACUUM ARC PLASMA CENTRIFUGE FOR ELEMENT AND ISOTOPE SEPARATION.** An arc was produced in a 30-cm-diameter, 4-m-long cylindrical chamber with coaxially mounted electromagnets providing a 2.6-m-long constant axial magnetic field of up to 6 kG. A pulse-forming network of 70-m $\Omega$  impedance provided nearly constant-current discharge pulses of several kA and 6-12-ms duration. The magnetized plasma column, flowing axially from the anode with a typical velocity of 10<sup>6</sup> cm/s, rotated nearly as a solid body. A typical rotation frequency was 10<sup>5</sup> rad/s. The centrifugal

effect due to the rotation caused a radial redistribution of ions within the plasma column, thereby producing elemental and isotope enrichment. The separation increased exponentially with the square of the radius. Enrichments of up to 300% were measured in a Cu-Zn plasma. The radial plasma density profile was roughly Gaussian, with central electron densities of about 10<sup>13</sup> cm<sup>-3</sup>. The radial potential profile across the column was parabolic with radius. These observations can be accounted for by a steady-state multispecies fluid model of the rotating plasma. 6 refs.

**079227 EFFECT OF AN OXYGEN PLASMA ON UNCOATED THIN ALUMINUM REFLECTING FILMS.** Thin aluminum films have been considered for use as a reflective surface for solar collectors on orbiting solar dynamic power systems. A matter of concern is the durability of such reflective coatings against oxidative attack by highly reactive neutral atomic oxygen, which is the predominant chemical species in low earth orbit. Research to date has been aimed at evaluating the protective merit of thin dielectric coatings over aluminum or other reflective metals. However, an uncoated aluminum reflector may self-protect by virtue of the oxide formed from its exposed surface, which constitutes a

physical barrier to further oxidation. This possibility was investigated, and an attempt was made to characterize the effects of atomic oxygen on thin Al films. It was found that long-term specular reflectance for uncoated aluminum exceeded that of Al and Ag reflectors with dielectric coatings. (Edited author abstract) 5 refs.

**079229 ECR PLASMA IN A HIGH POWER MILLIMETER-WAVE BEAM (REPORT IV) - CONTRIBUTION OF HIGHER HARMONIC RESONANCE HEATING.** Remarkable contribution of the 2nd and the 3rd harmonic resonances to the heating of electrons has been clarified experimentally by the radial launch of the millimeter-wave beam to the plasma. While existence of the fundamental (1st harmonic) resonance within the vacuum chamber is verified to be necessary for the efficient ignition of the plasma, irrespective of the wave launching position and/or direction. The heating is observed to be most effective in the resonance zone through which the wave propagates in the first passage, whether it is the 2nd or the 3rd harmonic one. (Author abstract) 2 refs.

**079234 CRITICAL RESUME OF PRESENT KNOWLEDGE ABOUT RECOMBINATION OF IONS AND ELECTRONS ON GLASS EXPOSED TO POSITIVE COLUMN PLASMAS.** This paper contains a critical summary of what is known about the recombination of positive ions and electrons on glass surfaces exposed to plasmas, with special reference to positive columns. There are still outstanding problems of a fundamental character. In particular, although the rate at which recombination has to occur is calculable from the plasma and wall-sheath parameters, the recombination coefficient is proving hard to determine except as a function of another unknown quantity, the gross positive surface charge density. Again, although the kinetics of the processes by which the ions reach their surface sites and the electrons approach them are reasonably clear, details of how they ultimately recombine are not. (Edited author abstract) 5 refs.

Coulter, J.R.M. (Queen's Univ of Belfast, Belfast, North Irel); Emeleus, K.G. *Rev Roum Phys* v 32 n 4 1987 p 399-403.

**079235 ION-ELECTRON RECOMBINATION IN A NEON, MEDIUM PRESSURE STATIONARY PLASMA.** The paper reports quantitative results on the losses of the charge carriers in a medium pressure, neon plasma. The results show that for pressures of about 15 Torr the recombination losses are as important as the diffusion losses while for pressures of about 30 Torr the recombination losses overtake the diffusion losses. (Author abstract) 6 refs.

**079236 ON THE DOUBLE LAYER DYNAMICS IN COLLISIONLESS PLASMAS.** As it is known, double layers (DLs) formed in collisional and collisionless plasma are involved in the appearance of different kinds of plasma instabilities. One of these, the so-called relaxation instability observed in certain conditions in a Q-machine plasma, was explained considering a DL formed near the plasma source which moves towards a cold plate positively biased with respect to the plasma source. It was further found that the so-called anode instability involves also the presence of DLs whose moving direction is away from the positively biased electrode (anode). The aim of this paper is to explain this apparent contradiction concerning the DLs moving direction and to show that in both cases the DLs dynamics involves the same phenomena. 11 refs.

**079237 HELIAC EQUILIBRIA.** Three-dimensional numerical calculations of Heliac equilibria are presented. The results indicate that finite- $\beta$  distortions in the flux surfaces can arise because of the presence of low order rational surfaces within or near the plasma. These distortions

arise as a result of nonlinear beatings between the toroidal shift and the helical components of the magnetic field. Reducing the toroidal shift by increasing the number of field periods and/or the aspect ratio improves the equilibrium  $\beta$ -limit. (Author abstract) 13 refs.

**079238 CHEMICAL TRANSPORT IN NON-ISOTHERMAL LOW PRESSURE PLASMAS.** Application of non-isothermal plasmas broadens the range of heterogeneous systems in which chemical transport reactions can occur. Kinetically irreversible systems can be utilized if a weak glow discharge is applied in the gas phase. Intense glow discharges, which can completely change the chemistry of a given heterogeneous system, are suitable for opening up new reaction routes via radicals in systems which are strongly endothermic without plasma. Examples are discussed to illustrate these possibilities. (Edited author abstract) 19 refs.

Veprek, S. (Univ of Zurich, Zurich, Switz). *J Less Common Met* v 137 Feb 1 1988 p 367-373.

**079239 SIMULATION STUDY OF ULTRA-LOW-q DISCHARGE PROCESS.** MHD phenomena in ultra-low-q (ULQ;  $q < 1$ ) discharges are extensively studied by means of three-dimensional magnetohydrodynamic (MHD) simulations. ULQ discharges are operated in the intermediate current range between the tokamak and the reversed field pinch. It is shown that ULQ dynamics is a competitive process between resistive diffusion and MHD activities: the former leads to current profile peaking ( $dq/dr > 0$ ) and the latter to current profile broadening ( $dq/dr < 0$ ). The MHD activity of ULQ discharges is studied, and it is found that the key process is non-linear growth of an  $m = 1$  ideal kink instability. It is observed that after the MHD activity has organized a global model stable state, resistive diffusion dominates the ULQ dynamics on the diffusion time-scale, leading to a global mode unstable state; then, MHD activity appears again. (Author abstract) 23 refs.

**079240 THEORY OF CLUSTER SYSTEMS IN PLASMA-LIKE MEDIA.** The conditions of existence of stable formations of charged particles (clusters) moving in a plasma-like medium are discussed in this paper. The interaction of clusters is considered in the framework of a one-dimensional model. It is shown that the stability of a cluster depends strongly on the number of particles that form part of it. When two clusters moving with respect to each other interact, they break up if the relative velocity is fairly low. Fast-moving clusters hardly interact with each other. (Author abstract) 10 refs.

**079243 VERSATILE MICROWAVE PLASMA APPLICATOR.** This paper describes a device used for the introduction of microwave energy into a plasma chamber over a wide area with high transfer efficiency and good energy uniformity. The applicator design was based on a slotted waveguide combined with a quartz window. The impedance properties were calculated for slots in the broad wall of a WR430 waveguide. Low-power simulating tests were conducted to determine the optimum geometry. A simple test system was used to measure and plot the three-dimensional spatial energy distribution. (Author abstract) 4 refs.

**079244 THEORETICAL MODEL OF THE HALO PLASMA OBSERVED IN A SMALL ASPECT RATIO FRC PLASMA.** A halo plasma, which is a low density plasma surrounding field reversed configurations (FRC), was observed in the Staged Theta Pinch-Linear experiment. As long as the plasma is kept free from the end walls with the help of a guide field structure, azimuthal ion flow builds up in the halo. The direction of the ion flow at the edge of the halo is opposite to that in the vicinity of the separatrix. This double structure of the ion flow can be explained by a model which assumes that the halo plasma is formed by energetic ions shuttling between the FRC and the open field region. The numerical results are in good agreement with the experiment. The model also suggests that the FRC has a good confinement ability for energetic particles if the plasma is not in contact with the discharge tube. (Author abstract) 15 refs.

**079245 MHD ANALYSIS OF HIGH  $\langle \beta_T \rangle$  DISRUPTIONS IN PBX.** Princeton Beta Experiment (PBX) discharges run at the lowest  $q$  and highest  $\langle \beta_T \rangle$  always terminated in a hard disruption. The discharges, with  $\langle \beta_T \rangle$  value of up to 5.5% and  $q$ -values down to 2.2, were obtained by employing large current ramps and large gas feed rates during neutral beam injection. Previous work has indicated that the achieved  $\langle \beta_T \rangle$  values were consistent with the limit imposed by the  $n=1$  ideal external kink with a conducting wall at  $b/a=2$ . The authors of the paper investigate further the validity of ideal MHD theory in explaining the low  $q$  disruptions. (Edited author abstract) 13 refs.

**079247 SIZE OF THE VIRTUAL SOURCE BEHIND A CONVEX SPHERICAL SURFACE EMITTING A SPACE CHARGE LIMITED ION CURRENT.** A plasma source fitted with a circular orifice and emitting a space charge limited ion current can be made to operate with a convex spherical plasma boundary (meniscus) by approximately adjusting its extraction parameters. In this case, the diameter of the virtual source behind the meniscus is much smaller than the orifice diameter. The effective value of this virtual source diameter depends significantly on various practical factors that are more or less controllable. Its lower ideal limit, however, depends only on the ratio  $\delta$  of the interelectrode distance to the meniscus curvature radius and on the ratio  $\omega$  of the initial to final ion energy. This ideal limit is given for the ranges  $0.1 \leq \delta \leq 10$  and  $10^{-7} \leq \omega \leq 10^{-3}$ . Preliminary experimental results are reported. (Author abstract) 8 refs.

## Acceleration

**079248 ACCELERATION OF COMETARY PLASMA IN THE VICINITY OF COMET HALLEY ASSOCIATED WITH AN INTERPLANETARY MAGNETIC FIELD POLARITY CHANGE.** Based on the ion plasma and magnetic field observations of Vega-1 near its consistent scenario is developed according to which the observed magnetic field topology, the observed burst of ions at energies 200-600 eV, and the observed directional dependence of the flow of these ions leads to the conclusion that these burst-particles are cometary ions which have been accelerated by the process of merging of magnetic field lines of opposite polarity. (Author abstract) 12 refs.

**079249 NUMERICAL ANALYSIS OF MPD ARCS FOR PLASMA ACCELERATION.** The characteristics of the arc region of a plasma thruster are investigated by the numerical solution of coupled MHD equations. The flow is assumed to be two-dimensional, but all other realistic effects are included, i.e., the Hall effect, ion slip, and other dissipations such as viscosity, thermal conductivity, and electrical resistivity. The results show the current concentration at the trailing edge of the anode and the raised temperature of the area. The Hall current causes harmful effects by lowering the thrust efficiency and eroding the electrodes. The thermal diffusion is beneficial in that it raises the thrust efficiency and prevents the erosion of the electrodes. 5 refs.

**079254 GROSSTECHNISCHE ANWENDUNGEN VON LICHTBOGENPLASMAVERFAHREN IN DER CHEMIE.** [Large-Scale Engineering Applications

of the Arc Plasma Process in the Chemical Industry]. Although employed in chemistry for almost 200 years, the principle of electric discharge is still being used on an empirical basis. Reliable mathematical relationships similar to those permitting the scaling-up commonly used in chemical process engineering are absent here. Part 1 of this paper, apart from outlining the apparatus required, deals with the difficulties encountered in the development and operation of industrial plasma generation of industrial plasma generators. A number of applications are described. The economic significance of plasma processes is briefly dealt with. (Author abstract) In German.

Mueller, R. (Huels AG, Marl, West Ger). *Elektrowaerme Int Ed B* v 45 n 3-4 Jun-Aug 1987 p 146-154.

**079255 NEGATIVE IONS IN INDUCTIVELY COUPLED PLASMA MASS SPECTROMETRY.** Basic characteristics of negative ions observed in ICP-MS have been evaluated and compared with those reported for positive ions. The types of ion species, ion sensitivities, background ions, and ion energies suggest that the negative ions observed in this study do not originate directly from the plasma but rather from electron capture or reaction downstream of the free jet expansion. It is shown that. 5 refs.

**079256 DECARBONIZATION BY USING ECR PLASMA.** Decarbonization rates were measured by the use of ECR plasmas of H<sub>2</sub> or O<sub>2</sub>. The rates are  $2.0 \times 10^{16}$  m<sup>-2</sup>s<sup>-1</sup> for H<sub>2</sub> and  $2.4 \times 10^{18}$  m<sup>-2</sup>s<sup>-1</sup> for O<sub>2</sub> at the same pressure of  $1.6 \times 10^{-2}$  Pa. The rate for O<sub>2</sub> is two orders of magnitude higher than that for H<sub>2</sub>. These results are analyzed depending on the equilibrium theory and the processing of decarbonization can be explained. (Author abstract) 11 refs.

**079257 PLASMA DEPOSITION PROCESSES.** The objective of this chapter is to provide the reader with a perspective on the unique features and the inherent limitations of the plasma deposition process for macroelectronic applications. The emphasis here will focus on the practical aspects of plasma deposition. First, the unique characteristics of the plasma process as a deposition technique will be reviewed and compared to other physical vapor deposition processes. In a subsequent section, attention will be given to the practical requirements of the plasma reactor itself, as well as its most important peripheral hardware, such as pumps and gas-handling equipment. We briefly review the use of the diagnostic tools as they are commonly used to enhance the reproducibility and reliability of the process. Finally, because the process has considerable commercial potential for a variety of practical applications, some of the scale-up issues and the economics of the process will be considered. 69 refs.

**079258 PLASMA EROSION OPENING SWITCH OPERATION AT LONG CONDUCTION TIMES.** The conduction time of the plasma erosion opening switch (PEOS) has been extended to carry mega-ampere currents for several hundred nanoseconds. The dependence of the peak conduction current on PEOS parameters and the results of magnetic probe and load voltage measurements are all consistent with PEOS theory. They indicate that the PEOS operating mechanisms at these long conduction times are the same as those operating in previous experiments at shorter conduction times. Translation of

the switch plasma into the load region, due to  $j \times B$  forces during the conduction phase, was not observed in this experiment. 19 refs.

**079260 BEAM-PLASMA INTERACTION IN CONDITIONS OF THE CHERENKOV COLLECTIVE EFFECT.** An analytical solution is given for the problem of the interaction of 'thin' completely magnetized plasma and an electron beam in conditions of the collective Cherenkov effect. The saturation mechanism of the beam-plasma instability in the given conditions is elucidated. (Author abstract) 6 refs.

Aleksandrov, A.F.; Kuzelev, M.V.; Khalilo, A.N. *Moscow Univ Phys Bull* v 42 n 4 1987 p 113-116.

**079261 NUMERICAL MODELING OF THE DYNAMICS OF ELECTRON BEAM IN PLASMA.** The method of large particles is employed to study the two-dimensional dynamics of an electron beam injected in a plasma. Evolutions of current and of the transverse profile of beam current density and the effects due to betatron oscillation of the beam particles, under conditions of charge and current neutralization are discussed in detail. A beam instability corresponding to the 'intersection' of the nonresonance electron-electron instability and filamentation instability has been revealed and studied. The quasistationary state of the nonlinear stage of instability has been analytically studied. (Author abstract) 13 refs.

Al'terker, B.A.; Zheksemin, S.R.; Rukhlin, V.G.; Tarakanov, V.P. *IVTAN Rev* v 1 n 2-4 1987 p 291-327.

**079262 NONLINEAR FREQUENCY SHIFT AND SPECTRAL WIDENING OF OSCILLATIONS EXCITED BY AN ELECTRON BEAM WITH AN ANOMALOUS DOPPLER EFFECT.** The nonlinear dynamics of a multimode relativistic beam-plasma system are investigated in conditions of an anomalous Doppler effect. It is shown that there is a substantial widening of the oscillation spectrum during development of instability. In this case the electron beam is slowed to a unit of the phase velocity of the excited wave. Asymptotic formulas are cited for the spectra of electromagnetic and beam waves. (Author abstract) 3 refs.

**079264 NUMERICAL MODELING OF THE PROPAGATION OF A QUASI-STATIONARY RELATIVISTIC ELECTRON BEAM IN A RAREFIED PLASMA.** Propagation of a quasi-stationary, charge-neutralized relativistic electron beam in a nondissipative medium is examined on the basis of a simple numerical model. The acquired results are compared with solution of the envelope equation and the results of other authors. (Author abstract) 5 refs.

Nauryzbaev, A.E. *Sov Phys Lebedev Inst Rep* n 6 1987 p 80-83.

**079265 EXCITATION OF IONS IN DENSE PLASMA BY ELECTRON IMPACT.** The (1s-2s), (1s-3s), (1s-2p), and (1s-3p) scaled excitation collision strengths in the presence of a dense plasma have been calculated including the effect of exchange in the framework of first-order theory. The effect of exchange is found to reduce the collision strengths further over the Born approximation results, only at high energies. The effect of exchange is found to persist in the energy range considered (up to the scaled incident energy  $E/Z^2 = 6.0$ ). The variations of collision strengths with change of screening parameters have also been reported. (Author abstract) 7 refs.

Sarkar, K.P. (Gurudas Coll, Calcutta, India); Basu, Madhumita; Ghosh, A.S. *Indian J Pure Appl Phys* v 25 n 9 Sep 1987 p 358-362.

**079266 PROBABILITY-MAXIMIZATION THEORY FOR A HIGHLY TURBULENT BEAM-PLASMA SYSTEM.** A new approach to the theoretical study of turbulent behavior of a collisionless plasma is developed. This approach is based upon the concept or probability maximization originally applied to collisional gases by Boltzmann. The probability-maximization theory deals with stochastic processes in a steady turbulent plasma by solving for the most-probable distribution. Our theory as applied to counter-streaming electron beams can quantitatively predict beam retardation, i.e. a decrease in the mean velocity of electrons injected from the system boundary. This is also in agreement with the results of a one-dimensional numerical experiment performed for such a beam-plasma system. (Author abstract) 20 refs.

Nakamura, Tadas (Univ of Tokyo, Tokyo, Jpn); Yamamoto, Takashi. *J Plasma Phys* v 38 pt 3 Dec 1987 p 483-493.

**079267 ELECTROSTATIC POTENTIAL INDUCED BY A FAST CHARGED PARTICLE PASSING PARALLEL TO A PLANAR SHEET OF TWO-DIMENSIONAL PLASMA.** This paper presents a calculation for the screened electrostatic Coulomb potential of a fast particle interacting with a sheet of two-dimensional (2D) plasma. The particle motion is taken to be parallel to the 2D plasma sheet and the plasma is in its ground state. The density perturbation response properties of the plasma are described in the random phase approximation. The screened effective potential is calculated as a function of the distance of the particle from the plane of the 2D plasma and its velocity. (Author Abstract) 17 refs.

Gumbs, G. (Univ of Lethbridge, Alberta, Can). *Solid State Commun* v 62 n 5 May 1987 p 365-368.

**079268 REFLECTION OF ION WAVES FROM A BIPOLAR ELECTRODE IN AN ION BEAM-PLASMA SYSTEM.** Wave reflection in an ion beam-plasma system was studied using a bipolar electrode as a reflector. For an incident beam mode, both the beam and the ion acoustic modes were observed. It was found that these reflected waves depend on the energy distribution of the reflected ions. Wave excitation by a grid is also discussed. (Author abstract) 16 refs.

**079269 TIME EVOLUTION OF THE VELOCITY DISTRIBUTION OF NEUTRAL-BEAM-INJECTED IONS HEATED BY ICRH IN A TWO-COMPONENT PLASMA.** The time evolution of the distribution function of the beam-injected particles in the presence of ICRH in a two-component plasma is determined. Consideration is restricted to the time development during two complementary time periods: (i) the early time period, i.e.  $0 \leq t \ll \tau_g$ , and (ii) the quasi-steady state, i.e.  $t > \tau_g$ , where  $\tau_g$  is the slowing-down time for beam-ion-electron collisions. Explicit analytical solutions are obtained for anisotropic as well as isotropic beam injection. (Author abstract) 16 refs.

**079270 NONLINEAR INTERACTION BETWEEN AN ELECTRON-ION BEAM AND A DISSIPATIVE PLASMA.** The interaction between an electron-ion beam and a collisional plasma is investigated. It is shown that taking into account dissipation in the plasma stabilizes instabilities in the beam. The instability saturation amplitude as a function of the dissipation level in the plasma and the beam is investigated numerically and analytically. It is shown that the saturation level in a dissipative medium can exceed the saturation level in ordinary beam-plasma instability. (Author abstract) 9 refs.

**079272 FAST ION CONFINEMENT DURING HIGH POWER TANGENTIAL NEUTRAL BEAM INJECTION INTO LOW PLASMA CURRENT DISCHARGES ON THE ISX-B TOKAMAK.** The beam ion thermalization process during tangential neutral beam injection in the ISX-B tokamak is investigated. The classical model is tested in co- and counter-injected discharges at low plasma current, a regime where large orbit width excursions enhance the importance of the loss regions. To test the model, experimental charge exchange spectra are compared with the predictions of an orbit following Monte Carlo code. Measurements of beam-plasma neutron emission and measured decay rates of the emission following beam turnoff provide additional information. (Edited author abstract). 35 Refs.

Carnevali, A. (Oak Ridge Natl Lab, Oak Ridge, TN, USA); Scott, S.D.; Neilson, H.; Galloway, M.; Stevens, P.; Thomas, C.E. *Nucl Fusion* v 28 n 6 Jun 1988 p 951-966.

**079273 HEAVY ION BEAM TARGET CORONAL PHYSICS.** Numerical calculations of the heavy ion beam interaction with the low density plasma (corona) surrounding a small fusion pellet are discussed. As heavy ions enter the coronal plasma, they lose some of their electrons, and these stripped electrons, called 'drop-offs', constitute an electron beam with approximately the velocity of the ions. The interaction among the heavy ions, the drop-off electrons and the background electrons is investigated. The coronal density and temperature profiles are deter-

mined from one-dimensional hydrodynamic calculations, assuming classical ion deposition. The electron-electron and ion-electron cold two-stream instabilities are examined with one-dimensional particle-in-cell calculations. The results suggest that a strong coupling among the heavy ions, the drop-off electrons and the background electrons can exist; this leads to the creation of a non-Maxwellian electron plasma and significant electron heating. (Edited author abstract) 25 Refs.

Magelsen, G.R. (Los Alamos Natl Lab, Los Alamos, NM, USA). *Nucl Fusion* v 28 n 6 Jun 1988 p 967-979.

**079274 SPECTROSCOPIC STUDY OF ANODE PLASMAS IN A MICROSECOND ELECTRON BEAM DIODE.** Experiments have been performed to investigate the visible emissions (370-600 nm) from long-pulse electron-beam-driven carbon anode plasmas, and to correlate the spectroscopic evidence for ions with deviations of the diode current and voltage from Child-Langmuir behavior. The electron beams had peak voltages of -0.8 MV, current densities approaching  $10^3$  A/cm<sup>2</sup>, and pulselengths of about 1  $\mu$ s. A three-phase beam/plasma evolution process is described. 29 refs.

## Calculations

**079275 TIME-DEPENDENT SOLUTION OF BOLTZMANN EQUATION IN RF PLASMAS: A COMPARISON WITH THE EFFECTIVE FIELD APPROXIMATION.** Electron isotropic distribution function (idf) and related quantities in rf plasmas (CO, H<sub>2</sub>, Ne), calculated by solving the time-dependent Boltzmann equation, are compared with the corresponding values obtained by using the effective field approximation (efa). We show that the agreement between the two methods depends on the ratio between the applied field frequency and the lumped frequencies for impulse and energy dissipation. In fact, only at moderately high field frequencies are results obtained according to efa comparable with the corresponding ones obtained by the time-dependent solution and subsequent time averaging, while in the other cases differences up to two orders of magnitude are observed. (Author abstract) 11 refs.

**079276 NEW COLLISIONAL RELAXATION MODEL FOR SMALL DEVIATIONS FROM EQUILIBRIUM.** A new collisional relaxation model, applicable to small deviations from equilibrium, is established. In distinction from previous models, the new model involves three different collision frequencies for momentum transfer, energy transfer and randomization, extends the relaxation function to include the full pressure tensor rather than only its trace, and describes relaxation to individual rather than composite Maxwellian distributions. The model is applied to the kinetic theory of waves in a magnetized two-component plasma. As a particular example, magnetosonic waves are discussed for the sake of demonstrating a wave damping mechanism due to incomplete collisional activation of translational degrees of freedom. (Edited author abstract) 16 refs.

Stubbe, Peter (Max-Planck Inst fuer Aeronomie, Katlenburg-Lindau, West Ger). *J Plasma Phys* v 38 pt 1 Aug 1987 p 95-116.

**079277 KINETIC THEORY OF THE HIGH-FREQUENCY PART OF THE SLOW ELECTROMAGNETIC MODE IN WEAKLY IONIZED GAS-DISCHARGE ARGON PLASMA WITH INELASTIC COLLISIONS.** The spectral characteristics of the

high-frequency part of the slow electromagnetic mode, specific for plasmas placed in an external dc electric field, as well as the features of the corresponding instability, are analyzed for weakly ionized argon gas-discharge plasmas with E/n ranging from 25 to 150 Td, and with electron temperatures between 60,000 and 70,000 K. The analysis is based on the linear theory of perturbation, and the dynamics of the electrons is described by appropriately modified kinetic equations for the one-particle distribution function. Attention is focused on the collisional processes between electrons and neutrals, and both elastic and excitational collisions are taken into account. (Edited author abstract) 21 refs.

Zigman, V.J. (Inst of Physics, Belgrade, Yugosl); Milic, B.S. *J Plasma Phys* v 38 pt 2 Oct 1987 p 223-233.

**079278 GENERALIZED BALESCU-LENARD COLLISION OPERATOR.** The generalization of the Balescu-Lenard collision operator to its fully electromagnetic counterpart in A.W. Kaufman's action-angle formalism is derived and its properties investigated. The general form may be specialized to any particular geometry where the unperturbed particle motion is integrable, and thus includes cylindrical plasmas, inhomogeneous slabs with non-uniform magnetic fields, tokamaks and the particularly simple geometry of the standard operator as special cases. The general form points to the commonality between axisymmetric, turbulent and ripple transport, and implies properties (e.g. intrinsic ambipolarity) that should be shared by them, under appropriate conditions. Along with a turbulent 'anomalous diffusion coefficient' calculated for tokamaks in previous work, an 'anomalous pinch' term of closely related structure and scaling is also implied by the generalized operator. (Author abstract) 20 refs.

**079279 ELECTRON KINETICS OF COLLISION DOMINATED R.F. BULK PLASMA IN CO: THE ROLE OF SECOND-KIND COLLISIONS.** Electron energy distribution functions (EEDF) and related properties in the bulk region of the rf CO plasma at the reduced rf field frequency  $\omega/p_0 = \pi \times 10^7$  sec<sup>-1</sup> torr<sup>-1</sup> have been calculated by solving the time-dependent spatially homogeneous Boltzmann equation in the presence of second-kind collisions and have been interpreted on a microphysical basis. The results show that second-kind collisions (vibrational and electronic) strongly affect the temporal evolution of EEDF, of the mean energy, and of the mean collision frequencies for vibrational and electronic excitation processes, as well as for ionization. Furthermore, the effect of second-kind collisions on an approximate determination of the time-averaged EEDF in the rf bulk plasma using the so-called effective-field approximation has been estimated. **079280 REFLECTION OF METASTABLE ATOMS BY A GLASS WALL IN A POSITIVE COLUMN DISCHARGE PLASMA.** The laser-induced fluorescence-spectroscopy (LIFS) method has been applied to a dc discharge plasma, and the radial density distribution of metastable (<sup>2</sup> <sup>1</sup>S) helium atoms has been measured. It was found that the density did not tend to zero at the discharge tube wall. Rather, the density was about 20-30 percent of the value on the tube axis. Using the collisional-radiative model, the authors interpret this result. Two possibilities are suggested as the origin of this finite population at the wall, namely, 1) the helium ions which recombine at the wall converted partly into metastable atoms and 2) the metastable atoms were not quenched completely at the wall, but were reflected by a certain amount. It was found that the first process could not reproduce the experimental population distribution, while the second process with a reflection coefficient of the metastable atoms of 80-90 percent accounted for the experiment. **079281 EFFECT OF PROPANE ON ATOMIC SPECTROMETRIC SIGNALS IN THE DIRECT-CURRENT PLASMA.** The addition of small amounts of propane to the direct-current plasma (DCP) affects the emission signal of analyte species in the plasma. In the normal analytical region of the plasma, a reduction in emission is seen; this reduction can be accounted for by a decrease in excitation temperature caused by the propane in this region of the plasma. Above the analytical region, an enhancement in atomic emission is seen. The excitation temperature in this region of the plasma was found to remain unchanged when propane was added. The mechanism for the enhancement is thought to be the reduction of metal oxides to the corresponding free metal by carbon. (Edited author abstract) 12 refs.

**079282 HIGH-SPEED NUMERICAL CALCULATION METHOD FOR RATE EQUATIONS OF ABRUPTLY RECOMBINING PLASMAS.** A high-speed numerical calculation method for the rate equation of abruptly recombining plasmas is proposed. It is demonstrated that, compared with the conventional trial and error method, the presented method can shorten the computing time by a small factor for a hydrogen-like plasma. When there are more than two ion species, such as in a helium plasma, the computing time can be shortened by one or two orders by using the present method. We conclude that this numerical method is especially useful in studying the gain and the duration of the laser oscillation using a plasma composed of multiply charged ions or a mixed gas. 10 Refs.

**079283 PROGRESS ON THE FLEXIBLE DATA ACQUISITION SYSTEM AT TWO PLASMA PHYSICS LABORATORIES.** A description is given of RSX-DAS, a flexible CAMAC-based data acquisition software system that runs on a variety of PDP-11 architectures and under RSX-11 operating systems. The system has modular, multitasking, and concurrent processing features. The communication among 17 tasks is accomplished through parent/offspring tasking, event flags, and shared regions. The user interface to RSX-DAS consists of a set of user-friendly commands, indirect command files, and menus. The database consists of four static shared regions for the control of data acquisition and display, one dynamic shared region for the data of current shot, and data files for previous shots. The modularity of the CAMAC interface software allows operation on several CAMAC organizations, e.g., a parallel branch or some dedicated crates, and allows easy addition and subtraction of CAMAC hardware. 3 refs.

## Computer Simulation

**079284 MAGNETIC RECONNECTION IN A COLLISIONLESS PLASMA: EVIDENCE FOR THE CURRENT SHEET ACCELERATION.** The magnetic reconnection process in a collisionless plasma is studied based on a particle simulation. It is found that the magnetic field reversal and particle energization take place

mainly in the midplane of the outflow region and the particle acceleration by slow shocks is not important. This result is consistent with the collisionless reconnection model proposed by Hill. (Author abstract) 20 refs.

**079285 GRIDLESS PARTICLE SIMULATION USING THE MASSIVELY PARALLEL PROCESSOR.** A two-dimensional gridless electrostatic simulation code is developed for the Massively Parallel Processor (MPP), which consists of 16384 processors configured in a  $128 \times 128$  array with nearest-neighbor communication. The gridless model instead of the particle-in-cell (PIC) model is adopted on the MPP, since the gridless model can be efficiently parallelized on a via Discrete Fourier Transform which minimizes interprocessor communication. The advantage of the gridless model is that it can be easily developed for three dimensional simulation. Our results suggest that parallel processors have the potential for performing large scale plasma simulations. (Edited author abstract) 8 refs.

**079286 INTERMEDIATE-FREQUENCY FLUTE MODES IN A MAGNETIC QUADRUPOLE.** A dispersion equation is derived for flute modes with frequencies between the electron and ion bounce frequencies in a plasma confined to a magnetic quadrupole. Two intermediate-frequency flute modes which propagate in opposite directions along the quadrupole axis are predicted for the UMIST quadrupole. The possible excitation of a flute mode by self-interaction of a drift mode is considered. (Author abstract) 5 refs.

**079287 TWISTED COIL GEOMETRY IN PLASMA CONFINEMENT DEVICES.** In the present work, the techniques of differential geometry are used to determine the actual location of turns as they are wound on arbitrary surfaces. In the process, a set of natural winding coordinates is derived; the Biot Savart law for calculation of magnetic fields is expressed in terms of these natural coordinates. Next, the advantages of using a class of surfaces, called developables, for winding surfaces are discussed. A particular developable, called the rectifying developable, offers the additional advantages that the turns on it are geodesics and that wide flat conductors can be wound on it to minimize bending strains. Finally, the problem of windings with conductors of finite thickness is briefly discussed. (Edited author abstract) 5 refs.

**079288 PARTICLE CONFINEMENT AND ADIABATIC INVARIANCE.** The general problem of adiabatic invariance is discussed by using, as an example, the particle motion in a mirror magnetic trap. A new, resonant, adiabaticity parameter is introduced, which allows the reduction of the axisymmetric problem to the standard map, and which provides a sharp estimate for the chaos (instability) border in magnetic traps. Peculiarities of the particle diffusion out of the trap, due to the presence of the chaos border, are considered. The mechanism of slow Arnold diffusion in a non-axisymmetric field is explained, and some rough estimates are given, including

the impact of weak noise (gas scattering). (Author abstract) Refs.

**079289 TOROIDAL PLASMA CONFIGURATION WITH ANISOTROPIC PRESSURE.** The relation between various surface quantities required in hydrodynamic calculations, and the relation between the parallel and perpendicular currents in an arbitrary magnetic toroidal plasma configuration with scalar pressure, are generalized to the case of anisotropic pressure. Magnetic co-ordinates for hydrodynamic equilibria in this configuration are defined. A general expression for the mean velocity of diffusion through a magnetic surface, on the basis of the one-fluid magnetohydrodynamic equation with anisotropic pressure, is derived. (Author abstract) 15 refs.

Rizk, Hussain M. (Arabian Gulf Univ, Manama, Bahrain). *J Plasma Phys* v 38 pt 2 Oct 1987 p 209-222.

**079290 CONTAINMENT FORCES IN LOW ENERGY STATES OF PLASMOIDS.** The application of Hamilton's principle to the problem of the determination of the structure of low free energy state plasmoids is discussed. It is shown that Clebsch representations of the vector fields and representations involving side conditions on the functional result in the same sets of Euler-Lagrange equations. The relationship of these representations to the problem of containment forces in vortex structures (plasmoids) is considered. It is demonstrated that the lowest free energy state of an incompressible plasma is always Lorentz force and Magnus force free. For a compressible plasma obeying the adiabatic gas laws, the Magnus force is finite. Introduction of conservation of angular momentum as an additional side condition also results in finite containment forces. (Author abstract) 19 refs.

**079291 EFFICIENCY OF RF CURRENT DRIVE IN THE PRESENCE OF FAST PARTICLE LOSSES.** The effects of losses of fast electron current carriers are included in a calculation of the efficiency of RF current drive. The analytical expressions obtained for the current drive efficiency  $J/P_A$  and bulk heating rate  $P_D/P_A$  are explicitly dependent on the fast electron confinement time,  $\tau_F$ . In most present tokamak experiments, fast particle losses are predicted to reduce the current drive efficiency from 50% to more than an order of magnitude. However, in future fusion plasmas fast electron confinement appears to be sufficient to allow nearly ideal efficiencies to be achieved. (Author abstract) 4 refs.

**079292 IMPURITY INJECTION EXPERIMENT ON THE TEXTOR TOKAMAK: EFFECT OF DETACHED PLASMA ON CONFINEMENT TIME.** A marked increase in the confinement time of injected impurities was measured during detachment of the plasmas in the TEXTOR tokamak. Non-recycling, metallic elements were introduced via laser blow-off, and scaling studies were performed. As the electron density increased, a threshold was reached beyond which the decay time of the brightness of the injected impurity transition was seen to increase from 75 ms to greater than 500 ms. The detachment of the plasma appeared coincident with the onset of this long confinement regime. (Author abstract) 15 refs.

**079294 CONDITIONS FOR CONFINEMENT AND POSITIONAL STABILITY OF A Z-PINCH IN HIGH ORDER MULTIPOLE AND CUSP FIELDS.** Conditions for the existence of equilibria and their positional stability (axisymmetric  $m = 1$  model) are investigated for a generalized N-conductor Extrap configuration in the approximation  $N \gg 1$ . This kind of approach elucidates and exploits the boundary layer character of the external field influence on the plasma. It is shown that a 'confinement condition' (plasma inside the separatrix) in general can be expressed in terms of a restriction on the 'non-circularity' of the plasma. By an expansion in the non-circularity, an analytic expression for the growth rate of ideal MHD  $m = 1$  displacements, with an arbitrary current profile in the plasma, is derived, and non-expandable equilibria, including equilibria where the separatrix coincides with the plasma surface, are treated numerically. (Edited author abstract) 20 refs.

**079295 CONFINEMENT OF ANGULAR MOMENTUM IN DIVERTOR AND LIMITER DISCHARGES IN THE DOUBLET III TOKAMAK.** Angular momentum confinement has been studied in neutral beam heated limiter and divertor discharges in Doublet III. Scaling of the angular momentum time with plasma current and neutral beam power has been determined. For divertor discharges, the angular momentum confinement time and the energy confinement time are equal and scale in the same way. This suggests that a single mechanism governs the transport of both energy and angular momentum in divertor discharges. For limiter discharges, the angular momentum confinement time is less than energy confinement time and the scalings are dissimilar. In both limiter and divertor discharges the measured angular rotation speed profiles are consistent with the theoretical prediction that angular rotation speed is a function of the flux surface co-ordinate only and is independent of poloidal angle. **079298 PHENOMENOLOGICAL CONSIDERATION ON  $E \times B$  DISCHARGES.** In the decade between 1960 and 1970 many experiments were performed on confining ions in the  $E \times B$  field systems to obtain a thermonuclear reaction. This paper proposes to develop a theory of a small fluctuating electric field by which the electric field of the crossed field system is superposed. The resonance between the fluctuation and the motion of ions confined in the field system induces a convergence to a component of the ionic motion. As a result, under a certain condition, the chaotic ions in the field system form spokes. These phenomena (spoke formation process and spoke rotation) observed in  $E \times B$  devices are interpreted by comparing the theoretical results. (Edited author abstract) 9 refs.

**079301 INVESTIGATION OF MAGNETIC FIELD PROPERTIES IN THE HELICAL AXIS STELLARATOR: ASPERATOR NP-4.** Experimental measurements of the magnetic field properties of a helical axis stellarator were carried out. The results, together with the numerical calculation, are described herein. The toroidal device, Asperator NP-4, has a helical magnetic axis with a pitch angle of 45° and a multi-field period of  $n=8$ . The magnetic field of NP-4 is produced by the currents of helical solenoids and  $L=+1, -1$  helical windings. By an electron beam mapping of field lines, the existence of a high rotational transform angle and magnetic surfaces are confirmed and the position of the helical magnetic axis is obtained. The other fundamental magnetic properties such as the shear and the specific volume of the configuration are also deduced from the measurements. Numerical calculations lead to a good agreement with the results of the experiment. (Author abstract). 14 refs.

**079307 LOW-FREQUENCY FLUTE MODES IN A MAGNETIC QUADRUPOLE.** An eigenvalue equation is derived for electrostatic waves with frequencies below the ion bounce frequency in a plasma confined by a magnetic quadrupole. This integral equation for the electrostatic potential is developed to second order in the curvature and contains the effects of electron and ion temperature gradients. A dispersion equation for flute modes is derived from it. The present theory applied to the private flux region of the UMIST quadrupole predicts that low-frequency flute modes will propagate in the electron and ion diamagnetic drift directions. (Author abstract). 4 Refs.

Willett, Joseph E. (Univ of Missouri-Columbia, Columbia, MO, USA); Wu, Hsi-Shu. *J Plasma Phys* v 39 n 3 Jun 1988 p 503-510.

**079308 THREE-DIMENSIONAL EQUILIBRIA IN DRAKONS.** An analytic formula of the second-order equilibrium  $\beta$  limit for DRAKONS with triangular connectors of rectilinear elements (CRELs) with arbitrary pressure profile is derived. Its predictions for a parabolic pressure profile are compared with the full third-order numerical results, leading to a semi-analytic formula. The  $\beta$  limits obtained here are much lower than those obtained previously. Pressure profiles with sharper boundaries have lower  $\beta$  limits. The equilibrium is governed by the predominant quadrupole Pfirsch-Schluter current. Small deviations from the CREL condition have almost no effects on the equilibrium and thus the  $\beta$  limit. Optimal triangular CRELs are found. They give  $\beta$  limits slightly higher than those for the standard triangular CREL. Other possible ways of raising the  $\beta$  limit are also discussed. (Edited author abstract). 7 Refs.

**079309 EXPERIMENTAL STUDIES ON THE SUSTAINMENT OF SPHEROMAK PLASMAS BY AN INDUCTIVE DRIVE OF THE TOROIDAL CURRENT.** Sustainment of spheromak plasmas produced in an external equilibrium field has been demonstrated with a center current transformer (ohmic heating (OH) coil), which is used to inductively drive the toroidal current of the plasma. The OH coil is covered by a cylindrical metal liner that is electrically disconnected from the main vacuum vessel (spheromak mode). A dynamo effect, i.e., automatic generation of toroidal flux similar to that of a reversed field pinch (RFP), is observed. The measured MHD activity consists of multihelicity helical modes with toroidal mode numbers  $N = 1-3$ . In order to investigate the difference between spheromaks and RFPs in the MHD activity during sustainment, experiments have also been made with the metal line of the OH coil connected to the vessel (RFP mode). The dynamics of the MHD activities observed are compared simulation results and their implication for the dynamo effect is discussed. 19 refs.

## Cylinders

**079313 EXCITATION OF WHISTLERS AND QUASI-STATIC MODES BY AN ANNULAR ELECTRON BEAM IN A PLASMA CYLINDER.** A non-local theory of whistler and quasi-static mode excitation by an annular electron beam in a plasma cylinder is presented. Cerenkov and slow-cyclotron interaction are considered in the weak-beam approximation. The growth rate is found to be quite sensitive to the beam radius except in the case of slow-cyclotron interaction of quasi-static modes. The growth rate varies significantly with beam velocity in the case of Cerenkov interaction of quasi-static modes, but in other cases it is rather insensitive to the beam velocity. **079314 EFFECTS OF NBI POWER MODULATION ON PELLETT INJECTION INTO A CURRENT**

**FREE PLASMA IN HELIOTRON E.** Hydrogen pellets are injected into the current free neutral beam injection (NBI) heated plasma in Heliotron E to effectively increase the plasma density and the internal energy. The chord averaged density of the target plasma is about  $2 \times 10^{19} m^{-3}$ , and the density increase by pellet injection is  $(4-6) \times 10^{19} m^{-3}$ . During this process the plasma remains stable. Under the present operational conditions, the pellet reaches the central axis; the penetration depth ranges from 27 cm to 35 cm (the magnetic axis corresponds to 30 cm). To optimize the plasma parameters obtainable by pellet injection, the NBI heating power is modulated. It is found that the mode of operation in which pellets are injected at relatively low NBI power followed by a higher-NBI-power phase is preferable to that in which pellets are injected during a constant high power phase. The main reason for this difference is the penetration depth of the pellet in the plasma which determines the deposition profile of particles in the plasma. (Author abstract) 19 refs.

**079315 DETERMINATION OF THE DEUTERIUM PLASMA DENSITY RATIO  $n_d/n_e$  THROUGH NEUTRON MEASUREMENTS.** JET has been operating with deuterium plasma for the past two years, during which time neutron spectrometry has been applied as a diagnostic technique for determining the ion temperature for suitable discharges. Combining the 'neutron temperature' with the neutron yield determination made with a fission counter diagnostic permits the central deuteron to electron density ratio ( $n_d/n_e$ ) to be determined. It is found that this ratio, for ohmically heated discharges, appears to fall with ion temperature from about 70% at 2 keV to 40% at 3 keV. The addition of ICRF heating does not alter the density ratio. These findings are consistent with the observation that high temperatures achieved with Ohmic heating in tokamaks are correlated with high impurity levels. (Author abstract) 14 refs.

**079316 DENSITY FLUCTUATIONS IN PLASMA BY LASER INDUCED FLUORESCENCE METHOD.** A method based on laser induced fluorescence has been developed to measure the density fluctuation in plasma. An expression giving the intensity spectrum of light scattered by a turbulent plasma has been derived using hydrodynamical equations with nonlinear terms. An estimate of the relaxation time of the turbulence in the plasma can be made by correlating the expression with observed intensity spectrum. (Author abstract) 9 refs.

**079317 TEMPORAL FEATURE OF DENSITY PROFILE DETERMINED BY PONDEROMOTIVE FORCE IN A LASER PLASMA.** The quasi-steady density profile determined by the ponderomotive force in a laser plasma is studied. The dependences of the local density scale length, the lengths of upper and lower density shelves and the average density scale length at lower shelf on the incident light intensity and time are derived. It is shown that after the quasi-steady state is reached, with the lapse of time the lengths of upper and lower density shelves and the average density scale length at lower shelf rise, and the density scale length in the critical density region increases slightly. **079318 USE OF BALMER RADIATION FROM INJECTED NEUTRAL BEAMS FOR MEASUR-**

**MENT OF BEAM DEPOSITION AND PLASMA DENSITY PROFILES.** An analysis of the attenuation behavior of neutral beams injected for plasma heating is discussed, which yields a beam deposition profile for a known plasma density profile or which may provide a plasma density profile. The population of surviving beam trails at a penetration depth into a plasma is inferred from the excitation process of the fast neutrals. The excitation light is roughly independent of the electron temperature, and the line spectra can easily be distinguished by means of Doppler-shift spectroscopy. Hydrogenic neutral beams typically consist of three energy species (E, E/2, E/3) with different survival probabilities. By comparing the excitation light from each species at several points along the beam path, it is possible to decode information on the plasma density through which the beam has passed. On the other hand, if the plasma density profile is known from other diagnostics, the fast ion deposition profile can be obtained. A preliminary result of single-chord measurements in Doublet III is presented. (Author abstract) 13 refs.

**079319 NEW DENSITY DIAGNOSTIC METHOD BASED ON EMISSION LINE INTENSITY RATIO OF NEUTRAL HYDROGEN IN AN IONIZING PHASE PLASMA.** For high temperature hydrogen plasmas in the ionizing phase, the population density of the excited levels has been calculated for a wide range of electron densities and temperatures. In the calculation we employed the most recent and reliable cross-section data for excitation between discrete levels and the ionization cross-section data from these levels. The line intensity ratios calculated under conditions of optical thinness are presented graphically for the Lyman and Balmer series lines. The intensity ratios are found to be rather insensitive to the electron temperature for temperatures higher than 10 eV. These values may be used for determining the electron density in the region of  $10^{17} < n_e < 10^{21} m^{-3}$ , which is relevant to fusion research plasmas. Radiation loss from the plasma and energy loss from the plasma electrons are also presented for a wide range of electron densities and temperatures. (Author abstract) 22 refs.

**079320 ION ENERGETICS IN THE INNER COMA OF COMET HALLEY.** The cometary plasma in the magnetic barrier just outside the diamagnetic cavity which surrounds the nucleus of comet Halley is virtually stagnant. The outflowing neutral gas exerts an outward ion-neutral drag force on this plasma, which balances the inward magnetic pressure gradient force in the vicinity of the contact surface. The cometary ions are frictionally heated due to the relative motion of the ion and neutral gases. The ion flow velocity must have a few km/s non-radial component in order to explain the ion temperatures measured by the ion mass spectrometer on Giotto. (Author abstract) 18 refs.

**079321 TOMOGRAPHIC DIAGNOSTICS OF LOW TEMPERATURE PLASMA.** A brief survey of the results of a cycle of investigations by the authors on designing apparatus and software for emission tomography of low temperature plasma is presented. A description

is given of the method of determination of the spread function (SF) of the emission plasma tomography (EPT) - computer complex, and results of SF measurements in different regions of the computer operating field are presented. In the course of the reconstruction of the SF, modified algorithms of computerized tomography have been employed. They take into account substantially the positive character of the tomograms and include the techniques for reducing the high frequency components of the unknown image. Results of experimental investigations of physical processes in low temperature plasma are illustrated by some examples obtained for arc discharge in a laminar flow of gas. **079324 ELECTRON DENSITY MEASUREMENTS FROM STARK BROADENED EMISSION IN A SODIUM PLASMA PRODUCED BY LASER RESONANCE SATURATION.** Electron Stark broadening of the  $4d_{3/2}$ - $3^2p$  multiplet transition in a sodium plasma produced by laser resonance saturation is used for undertaking spatial measurements of the free electron density across and along the plasma channel created in sodium vapor of density  $10^{15}$ - $5 \times 10^{16}$  cm<sup>-3</sup>. From these measurements and measurements of the neutral sodium density within a heat sandwich oven, we are able to deduce the corresponding electron temperature. These temperatures compare favorably with the electron temperature estimated from a Boltzmann analysis of line intensities. These experimental results demonstrate that this LIBORS code is capable of predicting the 3-dimensional nature of this new mode of laser ionization with reasonable accuracy, and may also explain the low electron temperatures and free electron densities observed by other research teams. (Edited author abstract) 88 refs.

**079327 EVOLUTION OF RADIATION POWER PROFILES IN ASDEX H-MODE DISCHARGES.** The paper investigates bolometrically determined radiation power profiles, energy exhaust and impurity accumulation in the two types of H-mode in ASDEX. During the burst dominated H-mode, the repetitive burst-like energy and particle expulsion into the divertor prevents an increase of radiation within the outer half of the plasma minor radius. This type of H-mode arrives at an equilibrium state. During the burst free H-mode, the radiation power losses, unimpeded by bursts, grow over the entire plasma cross-section until this H-mode ends in radiation collapse. Impurity accumulation, resulting in central peaking of the radiation power profiles, takes place in both types of H-mode. The time evolutions of the central radiation power density and the predominantly responsible iron concentration are not significantly affected by the presence or absence of bursts. **079328 CASCADE FLUORESCENCES FROM LASER-EXCITED LITHIUM ATOMS IMMERSSED IN A STATIC ELECTRIC FIELD FOR PLASMA DIAGNOSTICS.** The Stark effect on a laser-pumped Li atom to the  $4^2D$  or  $4^2F$  level was studied by the observation of two cascade fluorescence of 610.4 nm ( $3^2D \rightarrow 2^2P$ ) and 323.3 nm ( $3^2P \rightarrow 2^2S$ ) under a static electric field in order to develop a spectroscopic measurement of the static or quasi-static electric fields in plasmas with a combined technique of Li-beam probing and laser-induced fluorescence (LIF). The excitation spectra and field dependencies of both lines were obtained and found to agree with the theoretical values obtained by solving the rate equations. It was also shown that a method for exciting the forbidden transition from  $2^2P$  to  $4^2F$  is so sensitive as to make it possible to measure an electric field as weak as approx. 100 V/cm. A practical method that is applicable to plasma devices is described, and the effect of the electron density on LIF is also discussed. (Author abstract) 14 refs.

**079329 PROPERTIES OF ECR PLASMA IN A SIMPLE MIRROR FIELD I - CORRELATION IN COLD AND HOT ELECTRON PRODUCTION.** The properties of an ECR plasma in various gas species have been clarified through soft X-ray and probe measurements. Soft X-ray measurements were performed on hot electron plasmas in the energy range of 1-15 keV and hot electron parameters were determined. Using data concerning cold plasma parameters determined from probe measurements, a close correlation was found in the production and/or heating of cold and hot electron components by changing the external parameters over a

wide range. (Author abstract) 10 refs.

**079330 PROPERTIES OF ECR PLASMA IN A SIMPLE MIRROR FIELD II - SPATIAL STRUCTURE OF THE PLASMA.** The spatial structure of an ECR plasma in a simple mirror field was experimentally studied. From axial measurements of the cold plasma parameters it was found that a plasma can be efficiently confined between the two resonance zones in the axial direction, rather than between the mirror throats, when the gas pressure is low enough to produce sufficiently hot and/or warm electrons. While measuring the radial distribution of low-energy soft X-ray emissions, it was verified that the 2nd-harmonic, as well as the fundamental, resonance zones contribute remarkably to the production of hot and/or warm electrons. (Author abstract) 1 ref.

**079331 BROADENING OF SPECTRAL LINES OF POSITIVE IONS OF NITROGEN AND OXYGEN.** A study was conducted into the theory of broadening of spectral lines of positive ions of nitrogen and oxygen in a plasma. The current status of the problem is reviewed. The approximate method of calculating the parameters of ion line broadening, previously proposed by the author, is further developed. The contribution by inelastic electron collisions is included in a Bethe-Born-Seaton approximation. The Gaunt factor for electron impact excitation is normalized anew on the basis of numerous quantum-mechanical calculations. 131 refs.

Kobzev, G.A. *IVTAN Rev* v 2 n 1 1988 p 57-95.

**079332 RADIAL DISTRIBUTION MEASUREMENT OF SiH<sup>+</sup> IN A LOW-PRESSURE SILANE PLASMA.** The radial emission intensity distribution of SiH<sup>+</sup> over the substrate of a low-pressure silane plasma was investigated for various substrate temperatures. Measured lateral intensities were converted to radial emission coefficients using an Abel inversion. The intensity near the center of the substrate was found to increase with  $T_s$  and yielded an activation energy  $E_a$  of 1.1 kcal/mole. This result is consistent with the value of  $E_a$  determined by laser-induced fluorescence measurements obtained previously. Radially resolved emission data obtained by varying the operating parameters of rf power, gas flow rate, silane/argon mixing rate, and total gas pressure provide a useful means of determining the conditions necessary to generate a uniform plasma. (Edited author abstract) 15 refs.

**079333 MEASUREMENT OF ABSORPTION LINE PROFILE BY LASER OPTOGALVANIC SPECTROSCOPY.** In plasma diagnostics, the gas temperature is usually computed on the basis of a measurement of the Doppler width of the emission line profile. This Doppler width is measured by a spectroscopic method, for example by means of a Fabry-Perot interferometer. For some time past the optogalvanic effect (OG) has found broad application as a new spectroscopic method. The high sensitivity of the laser OG method permits one to study the structure of high-lying and, therefore, low-density, energy levels; the transition frequencies between these levels fall in the IR region of the spectrum. This paper describes an experiment where the absorption line profile of neon at wavelength  $\lambda = 1.15$   $\mu$ m in a plasma in a hollow-cathode lamp of type LSP-1 was measured. The choice of the object under investigation was dictated by the presence of specific knowledge about the form of the profile and the width of selected line of neon; this is

important for analyzing the measurement method. A He-Ne laser is used as a probe source of radiation with power near 9 mW. The results presented here indicate the outlook of the laser OG method for measurement of absorption profiles by scanning absorption lines with a magnetic field. 8 refs.

**079335 FAST ALPHA DIAGNOSTICS USING PELLET INJECTION.** Alpha particles will interact with the ablation cloud surrounding an injected pellet via charge-exchange (CX) and nuclear reactions. The possibility of using helium neutrals resulting from CX interactions between the incident alphas and a carbon pellet ablation cloud to determine the fast alpha energy spectrum is discussed. The upper limit on the ablation cloud density necessary to avoid significant energy loss by the incident alphas due to scattering is considered. The results of a pellet penetration and ablation model and its implications for alpha diagnostics are examined. The conceptual design of a diagnostic system for the Compact Ignition Tokamak (CIT) is reviewed. Proposed alternative approaches, which include nuclear reactions and observation of singly ionized helium from CX reactions are presented. (Edited author abstract) 19 refs.

**079336 DIAGNOSTIC TECHNIQUE FOR MEASUREMENT OF PLASMA PARAMETER IN rf DISCHARGE.** A discharge model for rf plasma has been proposed. The microwave interferometer technique has been used to measure the steady state electron density by measuring the phase shift suffered by microwave signals in the plasma tube with and without plasma. The recombination coefficient for argon measured by delayed microwave scanning technique reported earlier has been used to measure the generation rate of this discharge. The rf electric field strength of this discharge is studied theoretically. With the knowledge of recombination coefficient and the field strength values of parameters like power absorbed, ionization frequency, electron-neutral collision frequency have been calculated. Using the amount of power absorbed in this typical rf discharge, the electron energy has been estimated from an empirical relationship. (Author abstract) 13 refs.

**079337 ANALYSIS OF LOW  $Z_a$  IMPURITY PELLET ABLATION FOR FUSION DIAGNOSTIC STUDIES.** The possibility of using low atomic number ( $Z_a$ ) impurity pellets such as carbon, lithium and beryllium as diagnostic probes for fusion grade plasma is investigated using an ablation model based on the vapor shielding phenomenon. It is shown that pellet injection velocities of approximately six kilometers per second would be required for penetration of a 1 mm sized carbon (diamond) pellet half-way into a CIT-like plasma. Properties of the high density ablation cloud surrounding a low  $Z_a$  pellet are discussed in relation to a diagnostic scheme that uses charge-exchange interactions of fusion-born

alpha particles with the ablation cloud to determine the local alpha energy distribution function. Pellet lifetime results are given and compared with experimental ones. (Author abstract) 20 refs.

**079339 MEASUREMENTS OF PLASMA X-RADIATION BY THE PHOTOELECTRON METHOD.** The authors used the photoelectron method to study plasma X-ray spectra and to determine the electron temperature of the plasma,  $T_e$ . The measurements were made on the T-13 tokamak and the OGRA-4 mirror trap using a five-channel photoelectron spectrometer in the 50 eV to 40 keV energy range with a time resolution of 1 to 20 ms. The results are in good agreement with data obtained by Thomson scattering and by the filter method, and also with calculations of  $T_e$  based on plasma conductivity. It is shown that at large modern facilities a photoelectron spectrometer with no load limit can record  $10^4$  to  $10^5$  times more photons in a given time interval than an X-ray pulse height analysis system. Moreover, the photoelectron spectrometer has low sensitivity to hard X-rays and neutron radiation and can therefore be used at facilities with reactor parameters in experiments with D-D and D-T plasma. (Author abstract). 25 Refs.
